Abolishing Penalties for Abortion.—The small canton of Basel-Stadt, the most northern point in Switzerland, has been debating for some time the question of striking induced abortion from the list of criminal acts. The council finally voted in favor of this against the protests of the medical profession, but was soon obliged to rescind its action, the agitation against the measure compelling the rejection of the bill at a second reading.

Tuberculosis Conference of the Northland.—The Nordiska Föreningen mot tuberkulos is to meet at Stockholm the last week in June. One session is to be devoted to convalescents' colonies and occupation, and treatment of laryngeal tuber-

culosis. Tuberculosis specialists from Denmark, Finland, Iceland, Norway and Sweden are expected. The conference has been called by the Svenska Nationalföreningen mot tuberkulos, whose address is Birger Jarlsgatan 22, Stockholm.

Tenth Scandinavian Congress of Internal Medicine.—The occurrence and treatment of visceral syphilis has been appointed as the main topic for discussion at this gathering of Scandinavian internists at Helsingfors in July, 1921. The address on syphilis of the central nervous system is to be by Dr. Hanssen of Bergen, the discussion to be opened by Professor Hagelstam of Helsingfors. Syphilis of the abdominal and chest organs is to be presented by Professor Jacobaeus of Stockholm, and the discussion to be opened by Professor Tallqvist of Helsingfors.

Rate of Exchange with Germany.—Some of our German exchanges publish week by week the current rate of exchange to be adopted by the physicians at watering places in charging foreigners for their services. The rate given by the *Medizinische Klinik* for May 9, just received, is as follows: "141 marks for Americans; 130 marks for Argentinians; 51 marks for Belgians; 96 marks for Danes or Norwegians; 119 marks for the English; 46 marks for the French; 129 marks for Netherlanders; 32 marks for Finlanders; 34 marks for Italians; 117 marks for patients from Sweden; 134 marks for patients from Switzerland and 126 marks for those from Spain."

Epidemics of Smallpox.—Glasgow has experienced a considerable epidemic of smallpox, and there is a fear that it will spread to other parts of Scotland. The situation was particularly alarming because of the fact that approximately 40 per cent. of the children under 14 years are unvaccinated. Of fifteen unvaccinated children who contracted the disease, five succumbed; and of the first seven deaths reported from the disease, only one was of an unvaccinated person. Two sources of origin have been traced: a ship from India and a ship from Egypt. An epidemic was prevailing in Calcutta early in the year, 396 deaths from smallpox being recorded in the two weeks ending January 31.

Appeal for Lebanon Hospital.—The Lebanon Hospital for Mental Diseases, Asfuriyeh, Syria, through its American committee, has issued an appeal for subscriptions to a fund of \$50,000 for necessary equipment and reconstruction. This hospital, the only asylum for the insane between Constantinople and Cairo, is maintained by voluntary contributions from American, British, Dutch and Swiss benefactors and is administered by an executive committee of members of the staff of the Protestant Syrian College at Beyrouit. Accommodations are provided for 150 patients, and admission is granted to any needy mental patient, irrespective of creed, race or nationality. Communications should be addressed to Mr. Robert B. Haines, Jr., secretary, 119 South Fourth Street, Philadelphia.

Tokens of the Gratitude of France.—The *Presse médicale* of May 19 gives a list of persons to whom the French government has recently awarded the Médaille de la Reconnaissance Française. Among them are ten American physicians and surgeons who are cited for having volunteered to care for the sick and wounded and lavished their services with the greatest skill and devotion. The list includes Drs. P. Keating, Wawa, Pa.; C. Mack, Boston; H. Feiss, neurologist; Major E. Johnstone, Honolulu; John Miller; C. Powers, Denver; P. Petree, Germanton, N. C.; Hunter Scarlett, Philadelphia; and T. Beebe, Boston and Miss Ida Shields, Arlington, N. J., whose medical services to the refugees were highly appreciated. The list includes further Dr. Louis MacNulty of Lima, Peru, "who served as assistant and often acting chief of Hospital 38, with zeal and skill."

Deaths in Other Countries

Dr. J. B. Miranda, for thirty-four years professor of pharmacy at the University of Santiago, Chile, author of works on the treatment of cholera, etc.—**Dr. R. Livi**, professor of anthropology at the University of Rome, the chief authority on anthropologic statistics in Italy, and inspector general of the army medical service in the Florence district during the war, aged 64.—**Dr. G. B. Locatelli** of Brescia, Italy, prominent in the fight against pellagra, alcoholism and venereal disease. Not long before his death he had presented the Associazione dei Dermosifilografi Italiani with 20,000 lire to found the Locatelli prize for work in this line.—**Dr. F. Schrakamp**, professor of social hygiene and medical legislation at the Akademie für praktische Medizin at Düsseldorf, aged 60.

Government Services

Work on Medical and Surgical History of the War

The initial steps for the preparation of the medical and surgical history of the World War will at once be taken by Surgeon-General of the Army, M. W. Ireland. As finally passed by Congress, the first appropriation for this work was reduced to \$50,000, but provision is made that the total cost of this history will not exceed \$150,000. As it will require at least two years to complete this work it is the understanding that Congress will provide additional money to carry on this important undertaking from time to time.

Examination for Medical Officers

In accordance with the provision of the recent Act of Congress on reorganization of the Army, including the Medical Department, an examination will be held July 7 for those who served as officers in the Medical Department during the World War. The age limit will be 58 years. All grades are open to appointment of those qualifying physically, morally and professionally after examination. Those who have already applied will be authorized by the War Department to appear before the nearest examining board. Applications from others must be received not later than June 23. Information is available at every military station and recruiting station, or it may be obtained by writing directly to the Surgeon-General's Office.

Hospitals for Public Health Service

The policy of the government for the construction of hospitals and care of former service men is outlined in the bill reported to the House of Representatives by Congressman Langley of Kentucky, chairman of the Committee on Public Buildings and Grounds. The bill provides for the construction of five hospitals, of which three shall be for the treatment of neuropsychiatric patients. One of these hospitals will be located in the central Atlantic Coast states, one in the region of the Great Lakes, and one in the north Pacific Coast states. Two shall be for the treatment of tuberculosis patients, one of which shall be located in the Rocky Mountain States and one in southern California. This bill has been prepared by the Committee on Public Buildings and Grounds after consultation with the Surgeon-General of Public Health Service, director of War Risk Insurance and other officials and is expected to meet all hospital requirements of the immediate future in behalf of soldiers of the World War. The bill authorizes the expenditure of \$10,000,000 for the construction of these various hospitals. It permits the remodeling or extension of existing plants and equipment owned by the government.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list L. signifies lieutenant; C., captain; M., major; L. C., lieutenant colonel, and Col., colonel.

BUENOS AIRES

(From Our Regular Correspondent)

April 27, 1920.

Food Adulteration

The whole city has been much exercised over the results of an investigation being carried out by the municipal authorities in regard to adulterated or spoiled foodstuffs now being sold in the open market. It was ascertained through factory inspections that a number of biscuit and breadstuff firms and confectioneries were using spoiled eggs in their products. There were seized from storage large quantities of decomposed preserves, cheese, etc., it being found that they were sold after being treated so as to make them tolerable. In other well known factories there were kept spoiled meats and fish, which it was intended to treat in the same way. The popular indignation at these facts reached its height when four persons died as a result of eating some spoiled food, and an attempt was made to break into the house where the food had been prepared. The investigation is being continued.

Murder of a Student in the School of Medicine of La Plata

The signs of academic disintegration, since the students have obtained virtually the right of appointing the governing boards, found serious expression recently at La Plata. For several reasons which have changed every once in a while, the students of the University of La Plata have been on a strike for some time. A large number, however, being in disagreement with this move, requested to be allowed to

take the examinations. On examination day the examining board was assaulted by the strikers, some shots were fired, and a first-year student, David Viera, aged 20, who was taking the examination, was killed. The dean of the school of medicine, Professor Belou, has resigned his position, and it looks as if the school would be closed.

School of Medicine of Rosario

The government has just opened a school of medicine at Rosario, having placed in charge Dr. Agudo Avila. In view of the importance of that city, it seems assured that the school will become very important. It will be located next to the Hospital Centenario, the funds for the building having been provided by public subscription.

Antimalaria Campaign

The summer campaign against malaria carried out by the national department of public health in Catamarca, Tucumán, Salta and Jujuy is coming to an end. During the campaign 192 kg. of quinin has been distributed, 1,500 kg. of oil was employed, and 1,400 mosquito nets were given away to poor people. The result in some places seems to have been good.

Anthrax Cases

There has been a decided increase in the number of cases of anthrax among workmen, which may be considered as industrial accidents. In 1910, fifteen cases were observed, while in 1918, there were 226 and last year, 113 cases and 18 deaths. The department of labor has recommended to the government that measures be taken to protect the workmen liable to contract this disease.

LONDON

(From Our Regular Correspondent)

May 15, 1920.

The Electric Sterilization of Milk

The Medical Research Committee has published a report on this subject by Professor Beattie of Liverpool and Mr. Lewis, lecturer on bacteriology of Liverpool. An independent trial of the matter was also made at Birmingham by Professor Leith. The experimenters agree in supporting the value of the proposed electrical method of sterilization. The Birmingham workers found that the electrical method showed a close parallelism to the old method of sterilization by heat, and are inclined to think that the current kills the bacteria by virtue of the heat which it generates. They were led to believe that in the electrical method the current raises the temperature of the milk more quickly; and since it passes through every part of the milk, the heat which it generates reaches every part of the milk at the same moment—an advantage over the simpler thermal method. The sterilizing power of the two methods is similar, though the electrical is quicker in action. Leith summarized his report by saying that "both the thermal and electrical methods have a high practical value and deserve consideration in any endeavor made to improve milk supplies. The thermal is simpler and cheaper, the electrical quicker in action." Leith suggested further that both methods could be made more efficient by grafting on them the practice of pasteurizing by two treatment applications, with rapid cooling of the milk after each, and that even with a single application the milk would store better if rapidly cooled after treatment. In the opinion of the Medical Research Committee, the experiments at Birmingham, though they entirely support the practical results obtained by Beattie and Lewis at Liverpool, were not complete enough on their bacteriologic side to settle finally the question whether the electrical current in this method has a direct bactericidal action or whether it acts purely as a

thermal agent. Sir Oliver Lodge, who superintended the electrical arrangements, was strongly of opinion that its action was purely thermal.

Pellagra in Egypt During the War

The controversy that exists as to the etiology of pellagra renders important the report of a committee appointed to examine the situation created in 1918 by the presence in Egypt of a large number of prisoners of war suffering from pellagra. It was found to be a deficiency disease due to insufficient assimilation of protein, and characterized by erythema and pigmentation of the exposed parts of the body, on the back of the hands first, a fortnight later the nose, later on the feet, these discolored patches being dry and not sweating even under pilocarpin. Profound disturbance of nutrition with early wasting of the muscles of the shoulder girdle, and progressively increasing fall in blood pressure follow. Loss of appetite is a very early symptom, and there is defective secretion of hydrochloric acid in the gastric juice. Herewith there is impairment of digestion, both gastric and pancreatic, malassimilation of protein and fat, and an increased bacterial growth in the intestine, with intermittent diarrhea leading to further loss of food ingested, but incompletely absorbed. Also the enhanced destruction of protein gives very foul-smelling stools and indican appears in the urine in increasing quantities; apathy comes on, perhaps melancholia, and the patient dies. The disease picture suggests suprarenal inadequacy, and, in fact, in the recorded cases the suprarenals averaged 15 gm. lighter in the pellagra cases than in the controls. There is no evidence of specific bacterial or protozoal infection. Death is due to some intercurrent infection—pneumonia, dysentery, tuberculosis or malaria accounted for 91 per cent. of deaths. The disease occurred in Turkish camps, not in the camps of Germans alongside, where there was money to buy extra food. Spot maps showed that there was no infection from place or person.

The important question was how this disease was to be prevented. Eighty-eight per cent. of the cases arose among newly captured Turkish prisoners, who before capture for months had available only two thirds of their normal ration, and had suffered "from long continued undernutrition," as their German general had reported the year before. Further, the protein of their diet came mostly from wheat, barley or maize, very little from meat. Now Hopkins and Willcocks, in 1907, showed that the chief protein of maize cannot keep rats alive, as it does not contain enough tryptophan, an amino-acid of the aromatic series; in 1913, Sandwith suggested that want of tryptophan might help to cause pellagra. The committee had the help of Prof. W. H. Wilson, of the Cairo School of Medicine, who has long been working at the different nutritional values of the proteins, which seem in part to depend on their individual amino-acids. For the making of epinephrin a benzene nucleus is essential. For the production of this the human organism depends on the hydrolysis of special proteins in the food supply, and even then the yield of tryptophan in this process may be broken up by an overwhelming bacterial flora in the duodenum. Every diet scale considers how much protein is necessary for the man of 70 kg., which is agreed to be 40 gm. daily. But that means grams absorbed, and for normal persons must be increased by one tenth; but experiment proved that for Turkish prisoners it required to be increased by one half, so that, even if they had received full rations, the Turks would have been underfed. But, further, they were fed on the wrong proteins. Wilson had calculated the "biologic value of the proteins" (B. V. P.) of various foodstuffs, and had found that, to replace 30 gm. of meat as protein supply in a man's diet, 34 gm. of rice-protein were necessary, 50 of beans, 76 of bread, and 102 of maize. Maize-eating people, therefore,

suffer from pellagra because it has the lowest biologic value of the proteins of all the cereals, and if damaged or decayed it is all the less nutritious and pellagra arises more quickly. Vegetable proteins are not so easily assimilated as those in meat, and, further, the beans for the prisoners were not at first well cooked. These difficulties were all adjusted, but it was found that men might escape pellagra on a particular diet while resting, but succumbed as soon as they worked hard; so the diet for heavy labor, though showing already sufficient calory value and vitamin content, had to be increased; then the pellagra ceased.

A Medical Centenarian

Dr. J. S. S. Logie of Kirkwall has celebrated his one hundredth birthday. He is the doyen of the British medical profession, having taken his degree at Edinburgh in 1842. He is also the oldest elder of the Church of Scotland.

Supplement to the Pharmacopœia

Since the publication of the 1908 edition of the French Pharmacopœia, a number of remedies have come into current use in therapeutics, and it therefore became necessary to inscribe these in the pharmacopœia. Nevertheless, in the supplement which has recently appeared, one searches in vain for mention of colloidal silver, emetin, bismuth carbonate and other substances. The omission is explained by the following fact: The committee of revision, nominated April 10, 1910, was on the point of issuing the supplement in its present form in August, 1914, when the war interrupted the work. Reorganized in November, 1918, the committee desired that no further delay occur in the printing, and it confined its work simply to such corrections as did not entail considerable changes.

The supplement is in two parts: The first (Addenda) contains the new articles to be inserted in the body of the Pharmacopœia; the second (Mutanda) comprises additions, corrections, modifications and deletions applying to a certain number of articles. Among the new substances are noticed veronal, stovain, novocain and antidysenteric and antimeningococcic serums. As for the modifications, these relate mainly to standards of purity required of certain substances. The committee has decided, in effect, that traces of impurities which are nearly inevitable in the industrial preparation of certain products are permissible whenever these do not result in attenuation, however slight, of the therapeutic activity of the drug. It is interesting to note a change in the maximum dose of sulphonal and trional, which has been fixed at 1 gm., instead of 2 gm.

Death of Glénard

Dr. Frantz Glénard, national correspondent of the Académie de Médecine since 1896, died recently at the age of 72. We owe to him much of our knowledge of visceroptosis (often called Glénard's disease) and the introduction and adoption in France of the treatment of typhoid fever by cold baths.

Franco-American Scientific Cooperation

Mention was made in a preceding letter (THE JOURNAL, Jan. 31, 1920, p. 338) of the cooperative spirit manifest in the scientific relations of France and the United States. Along the same line, it is interesting to note the reciprocal advancement of the scientific works and ideas of the two countries. Thus, Dr. J. Darier recently presented before the Académie de Médecine a translation of his *Précis de dermatologie* by Prof. Sigmund Pollitzer, New York, in the preface of which the translator pays homage to the French

school of dermatology and in particular to the Hôpital Saint-Louis. On the other hand, Dr. A. G. Guillaume has just published a monograph on the great sympathetic system with special reference to its biologic reactions (*Le sympathique et les systèmes associés*). The author has made extensive use of the facts revealed by the works of British and American investigators (Gaskell, Higier, Head, Sir Edward A. Schafer, Pottenger, Barker and others). I think it should also be remarked that the publication of the *Archives of Neurology and Psychiatry* was announced in the last number of the *Revue neurologique* in flattering terms.

American Gift to Bacteriologic Institute

An American philanthropist, M. Douglas Flattery, has recently donated to the Institut bactériologique de Lyon the sum of 100,000 francs, the interest of which shall serve as an annual grant to a student of the University of Lyons for the pursuit of laboratory studies of infectious diseases.

Foreign Students—For or Against

At the ninth Congrès des étudiants, which recently met at Bordeaux, the following resolution was adopted: That free enrolment be granted to necessitous students by increasing the charges to foreign students. This was undoubtedly fostered by the fear of competition with foreigners who might settle in France after completing their studies. Not the least regrettable feature is the fact that the students should be capable of thinking of such a restrictive measure at the risk of prejudicing French influence abroad. An exactly contrary view seems to be maintained in official circles; in fact, a recent decree sets forth the credits which will be accepted to exempt foreign students from the school requirements. Students who might seek such exemption will simply have to prove that they have an adequate knowledge of the French language.

Printing of Graduation Dissertations

Two deputies, M. de Menthon and M. Ducos, have called the attention of the minister of public instruction to the great expense entailed by the compulsory printing of university dissertations. They inquired whether twelve typewritten copies would not serve the same purpose as the obligatory printing of 110 copies. The minister replied that printing the dissertation should be continued if for no other purpose than to serve as exchange with the principal foreign universities. This exchange should hardly be abolished, as it is one of the best methods of scientific propaganda.

Marriages

ARTHUR JUSTIN G. HENDERSON, Kiester, Minn., to Miss Hazel Olson of Estherville, Iowa, May 18.

JOHN FRANCIS BENNETT, Burlington, Wis., to Miss Florence Elizabeth Mauer of Milwaukee, May 31.

LLOYD JAMES BLAKEMAN, Chicago, to Miss Louise M. Pabst of Blue Island, Ill., recently.

RALPH WENDELL MITCHELL to Mrs. Margaret MacKenzie, both of New York City, June 2.

EUGÈNE ALEXANDER MOULTON to Miss Margery Lagerquist, both of Chicago, recently.

CLINTON B. ELLIS, Kansas City, Mo., to Miss Lillian St. Clair of Chicago, May 1.

LENA AUGUSTA GERALDSON to Mr. Frederick H. Miller, both of Napa, Calif., May 24.

MORRIS L. WEINSTEIN to Miss Marion H. Liebshutz, both of Chicago, June 1.

IDA RUTH GOROV, Chicago, to William W. Policoff of Philadelphia, May 30.

HARRY LEON STEELE to Miss Mary Stuart Osgood, both of Detroit, June 2.

Deaths

William Pollock Crumbacker, Independence, Iowa; Medical College of Ohio, Cincinnati, 1882; aged 62; a member of the Iowa State Medical Society; superintendent of the Independence State Hospital since 1902; assistant physician of the Athens (Ohio) State Hospital from 1884 to 1889; and superintendent of the institution from 1890 to 1892; superintendent of the West Virginia Hospital for the Insane, Weston, from 1893 to 1897; a member of the American Medico-Psychological Association; and contributor of numerous articles to the literature of hospital management and neuropathology; died, May 14, from pneumonia.

William St. George Elliott, Pasadena, Calif.; University of the City of New York, 1863; aged 81; a graduate in dentistry from the Philadelphia Dental College in 1870; formerly professor of operative dentistry in the National Dental College, London, England; acting assistant surgeon, U. S. Army, and assistant surgeon of Volunteers during the Civil War; dental surgeon to St. Mary's Hospital, New York City; died, May 23.

George Lafayette Loope, Seattle; College of Physicians and Surgeons, Chicago, 1886; aged 73; formerly surgeon to the Gogebic Hospital and to the Wisconsin Central and Northwestern systems at Bessemer, Mich.; a veteran of the Civil War, and during the World War on duty with the U. S. Shipping Board; at one time a member of the Michigan State Board of Health; died, May 11.

Francis Xavier Straessley, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1894; aged 60; also a graduate pharmacist; a member of the Medical Society of the State of Pennsylvania; a member of the common council of Allegheny and later of Pittsburgh, and a member of the staff of St. John's Hospital, Pittsburgh; died in St. Francis Hospital, Pittsburgh, May 24.

Clarence Miles Godding * Providence, R. I.; Harvard University Medical School, 1883; aged 62; surgeon to the outpatient department of the Rhode Island Hospital; visiting physician and surgeon at the Providence Lying-In Hospital, and attending physician to the Dexter Asylum; died at the home of his daughter in Providence, May 28.

James Buckley Tweedle * Weatherly, Pa.; College of Physicians and Surgeons in the City of New York, 1865; aged 83; health officer of Carbon County; local surgeon of the Lehigh Valley Railroad; once secretary of Carbon County Medical Society; surgeon of U. S. Volunteers during the Civil War; died at his home, May 21.

Otto Edward Forster, St. Louis; St. Louis Medical College, 1881; aged 61; a member of the Missouri State Medical Association; once president of the St. Louis Board of Health, and police commissioner; a specialist in diseases of the ear, nose and throat; died in Barnes Hospital, St. Louis, May 17, from heart disease.

Edward Cranch * Erie, Pa.; Georgetown University, Washington, D. C., 1873; New York Homeopathic Medical College, New York City, 1875; aged 68; president of the Erie County Medical Society in 1919; consulting physician to Hamot Hospital, Erie; died, May 20, from aneurism of the aorta.

Ernest Eldred Wells, Stillwater, Minn.; Chicago Medical College, 1898; aged 49; a member of the Minnesota State Medical Association; formerly coroner of Washington County, and for the last year county physician; once an alderman of Stillwater; died, May 17, from pneumonia.

Amos F. Green, West Jefferson, Ohio; Starling Medical College, Columbus, Ohio, 1894; aged 60; a member of the Ohio State Medical Association; formerly mayor of West Jefferson, and coroner of Madison County; died, May 21, from acute nephritis.

Louis Henry Mayer * Johnstown, Pa.; Jefferson Medical College, 1887; aged 58; a member of the staff of the Conemaugh Valley Memorial Hospital; president of the Cambria County Medical Society in 1896; died, May 22, from heart disease.

George E. Pettet * Memphis, Tenn.; Memphis (Tenn.) Hospital Medical College, 1888; aged 63; a specialist in internal medicine; while crossing a street in Memphis, May 20, was struck by a street car and died while being taken to the hospital.

William C. Bundy, Modesto, Calif.; College of Physicians and Surgeons, Chicago, 1885; aged 74; for many years a practitioner of Aurelia, Iowa; died at the home of his daughter in Primghar, Iowa, May 12, from cerebral hemorrhage.

William C. Bell, Detroit; Detroit Homeopathic College, 1911; aged 33; a member of the Michigan State Medical Society; assistant surgeon to the police department of Detroit since 1917; died, May 19, from pneumonia.

Hanford Charles Keith, Losantville, Ind.; University of the City of New York, 1882; aged 62; a member of the Council of Physicians and Surgeons of New Brunswick in 1882; died recently from heart disease.

Frank Rufus Searles, New York City; Long Island College Hospital, Brooklyn, 1892; Columbia University College of Physicians and Surgeons, New York City, 1899; aged 72; died, May 5.

George LeRoy Menzie, Oneida, N. Y.; College of Physicians and Surgeons in the City of New York, 1866; aged 77; surgeon of U. S. Volunteers during the Civil War, died, May 12.

John Miller, Netcong, N. J.; University of the City of New York, 1886; aged 57; a member of the Medical Society of New Jersey; died, May 7, from myocarditis.

Edgar Albert Tobey * Youngstown, Ohio; Western Pennsylvania Medical School, Pittsburgh, 1904; aged 45; died in Los Angeles, March 25, from uremia.

Robert Graves * Chicago; Northwestern University Medical School, 1893; aged 50; died in Wesley Hospital, Chicago, April 5, from pneumonia.

George Milton Warren, Warren, Ont.; Victoria University, Coburg, Ont., 1870; aged 72; died at the home of his brother in Toronto, April 8.

Lon S. Keith, Benzien, Mont.; Eclectic Medical Institute, Cincinnati, 1887; aged 62; died, April 29, from pneumonia following influenza.

George M. Hoehn, Mount Airy, Cincinnati; Medical College of Ohio, Cincinnati, 1885; aged 67; died, April 21, from arthritis deformans.

Cotesworth Pinckney Smith * Arkansas City, Ark.; University of Louisville, Ky., 1873; aged 76; died, February 2, from heart disease.

Charles W. Barker, Baltimore; University of Maryland, Baltimore, 1885; died at the home of his daughter in Baltimore, May 9.

Francis Joseph Todd, Oakland, Calif.; University of Michigan, Ann Arbor, 1883; aged 59; died, April 27, from cerebral hemorrhage.

Edward M. Goodwin, Toledo, Ohio; Albany (N. Y.) Medical College, 1863; aged 77; died, March 18, from heart disease.

John B. Wilson, Scott, Ohio; Fort Wayne (Ind.) College of Medicine, 1889; aged 61; died, May 7, from valvular heart disease.

Cary Hamilton Wilkinson, Galveston, Texas; Jefferson Medical College, 1869; aged 75; died, February 3, from uremia.

William M. Kerr, Savannah, Mo.; Miami Medical College, Cincinnati, 1868; aged 80; a veteran of the Civil War; died, May 4.

Archimedes Rose, Vernal, Utah; Jefferson Medical College, 1879; aged 64; died, April 12, from valvular heart disease.

Hampton Pinckney Whatley, Mineral Wells, Texas; Barnes Medical College, St. Louis, 1904; aged 48; died, April 22.

David C. Fouts, Conrad, Mont. (license, Indiana 1900); aged 75; formerly of New Salisbury, Ind.; died, April 12.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

MORE MISBRANDED NOSTRUMS

Sealeaf Emulsion.—A shipment of this preparation, which the label described as "A Chocolate Cod Liver Oil," was made by the Sealeaf Emulsion Co., New York City, in September, 1917, in violation of the federal Food and Drugs Act. The Bureau of Chemistry analyzed the product and reported that it consisted essentially of cod liver oil with malt extract, chocolate, alcohol, aromatics and water. It was falsely and fraudulently represented as a cure for pulmonary diseases, coughs, colds and general debility; as a blood purifier and as a protection against lung trouble, rheumatism, weak kidneys, and all organic diseases; as a cure for asthma, bronchitis, and catarrhal affections and as a preventive and remedy for diabetes, malaria, gastritis, etc. In December, 1918, the company pleaded guilty and was fined \$50.—[*Notice of Judgment No. 6851; issued May 4, 1920.*]

Green Mountain Herb Tea, Sabine's Indian Vegetable Tea and Sabine's Indian Vegetable Cough Balsam.—Herman C. Lemke and Mary Sabine did business in Milwaukee, Wis., under the trade name A. J. Lemke Medicine Co. In September, 1917, this concern shipped quantities of "Green Mountain Herb Tea," "Sabine's Indian Vegetable Tea" and "Sabine's Indian Vegetable Cough Balsam." The Bureau of Chemistry analyzed these preparations and reported that the "Green Mountain Herb Tea" and the "Indian Vegetable Tea" consisted essentially of senna, fennel, elder flowers, anise, triticum, sassafras, American saffron, coriander, licorice root, butter-nut bark, buckthorn and Epsom salt. The "Indian Vegetable Cough Balsam" was found by the same chemists to consist essentially of alcohol, chloroform, tar, resins, sugar and traces of alkaloids, the whole flavored with aromatics. "Green Mountain Herb Tea" was falsely and fraudulently represented as a cure for indigestion, liver complaint, kidney complaint and diseases to which women and children are subject. It was also alleged to be a blood purifier, to prevent malarial disorders, to make new rich red blood and to strengthen and invigorate. "Indian Vegetable Tea" was falsely and fraudulently represented as a cure for sick and nervous headaches and indigestion, all scaly eruptions of the skin, pimples, scrofula, salt rheum, tetter, and the different diseases of delicate females and young children, as well as being good for some other things. The "Indian Vegetable Cough Balsam" was falsely and fraudulently rep-

resented as a cure for incipient consumption, whooping cough, all throat and lung complaints, bronchitis, coughs, colds, hoarseness, etc. In February, 1919, Herman C. Lemke pleaded guilty and was fined \$300. A *nolle prosequi* was entered as to Mary Sabine.—[*Notice of Judgment No. 6857; issued May 5, 1920.*]

Bovinin.—The Bovinine Co., New York City, shipped in July, 1917, to Porto Rico, a quantity of "Bovinin" that was misbranded. The Bureau of Chemistry reported that analyses showed that the product was apparently a meat extract. It was falsely and fraudulently represented as a cure for anemia, nervous prostration, neuralgia, asthma, alcoholism, heart disease, diseases of children, St. Vitus' dance, catarrh of the bladder, menstrual disorders, diabetes, chronic gastritis, consumption and a few other things. It was further declared misbranded because the label did not declare the quantity or proportions of the alcohol it contained. In December, 1918, the Bovinine Co. pleaded guilty and was fined \$50.—[*Notice of Judgment No. 6854; issued May 4, 1920.*]

Fruit-a-Tives.—In October, 1918, the United States attorney for the District of Massachusetts, acting on a report of the Secretary of Agriculture, filed a libel of information asking for the seizure and condemnation of 84 dozen packages of Fruit-a-tives that had been shipped by Fruitatives Limited, Ogdensburg, N. Y. The Bureau of Chemistry reported that analysis of a sample showed that it contained essentially extracts of aloes, nux vomica (strychnin) and cinchona bark (quinin). The nostrum was declared misbranded because the label and cartons conveyed the impression that the laxative properties of Fruit-a-tives were due to the presence of fruit or fruit extracts when in fact the laxative properties were due to aloes and nux vomica. Furthermore, the preparation was falsely and fraudulently represented as a remedy, treatment or cure for indigestion, kidney irritation, skin diseases, headaches, backaches, sleeplessness, pelvic pains, nervous depression, catarrh, etc. In November, 1919, the claim-

ant, having filed an answer and a sufficient bond for the release of the product, judgment of condemnation and forfeiture was entered and the product was delivered to the claimant.—[*Notice of Judgment No. 6884; issued May 4, 1920.*]

Anticalculina Ebrey.—This preparation was being sold in July, 1917, in Porto Rico by the Ebrey Chemical Works of Humacao, Porto Rico. The Bureau of Chemistry reported that analysis showed the preparation to consist essentially of alcohol (28.8 per cent. by volume) colchicin, ammonium salts, vegetable extractives and water. The preparation was falsely and fraudulently represented as having the power of dissolving calculi, both renal and biliary, and to be a cure for diseases of the liver, kidneys and bladder, Bright's disease, diabetes, rheumatism, jaundice, dropsy and other conditions. It was further declared misbranded because the

What is the Therapeutic Value of HYPOPHOSPHITES?

*A research conducted for the
Council on Pharmacy and Chemistry*
SHOWED

*There is no reliable evidence that they exert
a physiologic effect. It has not been dem-
onstrated that they influence any pathologic
process they are not 'foods.' If they are of any
use, that use has not been discovered.*

Fellows Syrup of Hypophosphites
is an affront to sound therapy
"Syrupus Roborans"
An unscientific shotgun mixture
"Robinson's Hypophosphites"
is exploited with unwarranted therapeutic claims
"McArthur's Syrup of the Hypophosphites Comp."
is an irrational preparation.

This is a greatly reduced reproduction of one of numerous educational posters shown at the New Orleans meeting in the exhibit of the Council on Pharmacy and Chemistry. The hypophosphites were introduced into medicine in '58 by Churchill, who advanced the theory, long since discarded, that the so-called tuberculous diathesis was due to a phosphorus deficiency. It is now known that little phosphorus, if any, is assimilated from hypophosphites—far less than from phosphorus compounds of ordinary food. Due to the power of advertising, many physicians still prescribe hypophosphite combination, although there is neither scientific basis, nor clinical evidence to warrant such prescribing.

amount of alcohol present was not correctly stated on the label and it was falsely branded as to the country in which it was manufactured, being produced in Porto Rico but labeled as coming from the United States. The Ebrey Chemical Works in March, 1919, entered a plea of *nolo contendere* and was fined \$50 and costs.—[*Notice of Judgment No. 6900; issued May 4, 1920.*]

McDowell Ginseng Bitters.—Douglas E. McDowell, who traded as the McDowell Ginseng Garden, Joplin, Mo., shipped in November, 1917, a quantity of "McDowell Ginseng Bitters." Analysis of a sample by the Bureau of Chemistry showed that the product was a slightly acid solution of plant extract containing small quantities of glycerin and a zinc salt. The preparation was falsely and fraudulently represented as an effective cure for all stomach troubles except cancer; for all intestinal disorders, constipation, cholera infantum, acute dysentery, congestion of the liver, all female disorders and also as a general sexual tonic for men and women. In June, 1919, McDowell pleaded guilty and was fined \$20 and costs.—[*Notice of Judgment No. 6897; issued May 4, 1920.*]

Correspondence

LUNCHEON GLIMPSES OF SIR WILLIAM OSLER DURING THE WORLD WAR

To the Editor:—It was my good fortune to come in rather close contact with Sir William Osler in 1915 during the World War. He was consultant to one of the hospitals in South Devonshire, England, where I was working, and during his visits to this section, which would sometimes last a week, he would have luncheon with us every day after his ward rounds. These luncheons were a delight, as Dr. Osler's conversation was always sparkling and brilliant and full of humor. It became my custom to jot down in my diary much of what he said. In picking it up the other evening I found his remarks highly entertaining, and it occurred to me that perhaps the readers of THE JOURNAL would find them equally so.

Dr. Osler returned after a month's absence. As he made his visit through the hospitals he generated everywhere a spirit of warm friendship. He shook hands with all the physicians and nurses as he came to them, not overlooking the probationers. To those across the ward he waved a friendly greeting. One of the nurses asked him to let her take his photograph, and he grasped the arms of two of the physicians, saying: "Well, but I must have the boys with me." A few moments afterward the nurse, watching her opportunity, snapped him by himself. When he heard the click of the camera he looked up in surprise and exclaimed, smiling: "Oh! you thief."

As he met the secretary of the hospital, a very quiet and demure English woman, he asked her if she were being treated as well as she deserved. She blushed and replied that she thought she was. Whereupon Sir William added: "Well, if you are not, just let me know and I shall see that your treatment reaches that standard."

I showed him eight patients with gunshot wounds of the chest and he examined them carefully and dictated a note on each and then remarked to me: "Turn them over to Dr. Rest and Father Time, and with the assistance of the nurses and the culinary department they will soon come around."

He became very much interested in an aneurysmal varix of the popliteal which gave a pistol shot sound in both femoral arteries. When we went to lunch he soon had himself surrounded by every book in our library which contained any matter on aneurysms.

All of us were waiting in the drawing room for lunch. Dr. Osler was sitting on the corner of a table clicking his heels together with the buoyancy of a schoolboy, when the lunch bell sounded. But no one moved for a moment, and then Dr. Osler quickly remarked to Lady Osler and Mrs. Herbert Hoover: "Why, these boys get up at 6 o'clock (he must have surmised that we got up at 8 o'clock!) and I know they are hungry. Let's go in to lunch."

With us this day was a professor of sociology of a Western university and his wife, who were spending a year abroad studying social conditions. The Carnegie fund for university professors was mentioned. Dr. Osler said: "It is a splendid thing and in many instances a life saver to the professors' wives. They (the wives) have a most trying profession," he added, "looking after us, for the best of us are a poor lot—simply treading on the fame of our predecessors, throwing dust in the students' eyes, but fortunately some of them find us out." One lady replied, "Why, Dr. Osler, I think you deserve all you receive. I have heard of Dr. Osler's book on medicine for so many years that I expected to meet an old man." Dr. Osler laughed and said: "Oh, that was my father. He was a fine old man!"

Dr. Osler then continued: "That reminds me of a time when two other doctors and I were sent on a committee down on the eastern shore of Maryland to investigate a matter. When we reached the small town where we were going, I was introduced to the doctor of the community, a splendid type of the old school, and as he gave my hand a cordial shake, he asked hesitatingly showing surprise that I did not have silver locks: 'Well, are you the Dr. Osler of Baltimore who has written that great book on medicine?' As quick as a flash I replied, 'Oh my, no, that was my father!' 'Well, I thought so,' he added; 'Now, you give the old man my regards and tell him that I certainly like the way he presented the subject of infectious diseases, especially pneumonia and malaria.' 'I shall surely do that,' I said, 'and I know father will be very gratified.' As we remained here several days we thought we would have to tell the old doctor the truth, but we didn't."

"One day on this same trip, we had just finished lunch and were in the office of the hotel, when some one rushed in and asked very excitedly if Dr. Osler were there and if he would come down to the shore, for a lady had fallen off the pier and she might be drowning. I immediately said that I did not know much about resuscitating drowned people, that was out of my line, but that one of the doctors with me was the Hopkins specialist in this branch. This doctor was hurried to the scene and the fat woman who had ventured out too far on the pier and had slipped into the water was soon quite restored. The Baltimore papers gave an account of the incident the next morning, declaring that the woman's life was saved because of the prompt action of this doctor, a specialist in resuscitating drowning people, who happened to be near the scene. The fat woman has never forgotten the doctor's heroic deed and always sends him on her birthday a grateful letter accompanied by a personal photograph. By this time he surely has a sufficiently large collection to start a photographic gallery."

During the meal something was mentioned about the English not eating hot bread, and Dr. Osler replied: "That is the reason most doctors in England are poor. Why, I used to make my living in Baltimore," he continued, "from the people who eat hot bread, just as the doctors in Boston make their living from people who eat pie. One time I had my secretary, a very intelligent woman and a hot-bread eater, of course, compile the histories of the patients who had come to my office for one year, and you would be surprised at the large percentage in whom hot bread was the cause of their trouble."

Then, just to make a deeper impression on his hearers and with a twinkle in his eye, he said, "I believe it came to 68.5 per cent."

The professor of sociology, a very able but decidedly underdeveloped and undernourished man, said he had been to see five specialists on account of stomach trouble. (I afterward learned that all five of the specialists had told him that his trouble was neurasthenia.) When the professor left, Dr. Osler remarked: "That man is a very smart fellow; but it was too bad that he couldn't have chosen his parents, for he has too much brain for his body."

Coming out from lunch we sat around smoking, and some one mentioned what the Rockefeller relief fund for the Belgians had accomplished. Dr. Osler remarked that it was rather peculiar how Mr. Rockefeller first became interested in Johns Hopkins. He said: "At dinner one evening in Baltimore, Mr. Gilman, president of Johns Hopkins, and Mr. Gates, Mr. Rockefeller's right hand man, were sitting side by side, and Mr. Gates remarked that not long ago he picked up, by chance, a book on medicine by a man named Osler, and, looking through it, he became so interested in it that he purchased a copy and enjoyed intensely reading the section on infectious diseases. Not long afterward he told Mr. Rockefeller how engrossed he had become in this book and that he wished to present him with a copy, which he did. Soon afterward, Mr. Rockefeller told Mr. Gates that he was surprised to know that medicine was such a wonderfully progressive science and to learn what good work this man Osler was doing in Baltimore. Mr. Gilman was naturally much interested in Mr. Gates' story, and when he had finished he said: 'Now, Mr. Gates, if you would sit down tomorrow and write Dr. Osler what you have told me, I am sure he would feel very gratified.' Accordingly, in a few days I received a letter from Mr. Gates to the effect of the foregoing. After reading it, I handed it to Mrs. Osler, saying: 'Please put this letter in the safe. There may come a time when it will prove of service.'"

Dr. Osler went on to say: "A few years later when the Baltimore fire occurred and subjected the Hopkins Medical School to such a loss, I asked Mrs. Osler to look up the letter from Rockefeller's man. The letter was readily found and I wrote immediately to Mr. Gates, saying: 'You are doubtless aware of the awful fire which has visited Baltimore and of the loss which Hopkins has sustained. Several years ago you wrote me a very interesting letter, and it just occurred to me that probably you could interest Mr. Rockefeller in considering our unfortunate position at this time.'"

"A few days later I received a telegram saying: 'Our Mr. Murphy will be with you tomorrow.' And 'tomorrow' 'our Mr. Murphy' came and spent several days in making an accurate estimate of the Hopkins loss. In the evening we had him at the Maryland Club and showed him that we were pretty good fellows!"

"After Mr. Murphy's departure, several weeks expired. They seemed like months. We heard nothing, and our hopes had waned considerably, when I received a letter from John D., Jr., saying: 'My father has carefully considered your losses, which total \$430,000.67, and he wishes to know whether you would prefer to have a check or securities for the amount of \$500,000.' I immediately took my letter of good news around to the treasurer, and Mr. Rockefeller was informed that we would be pleased to receive a check for the \$500,000."

It was misting and cool, one day. Several of us were standing around the fire-place waiting for the lunch bell to sound. Just then Dr. Osler came in, bareheaded and without an overcoat. Lady Osler looked at him and exclaimed

in astonishment: "Why, Sir William, what do you mean by running around here in the rain, bareheaded and without an overcoat?" Sir William, who was just getting over a severe cold, evidently could find no plausible explanation for his carelessness, and replied, with a smile: "Well—ah—well, what's a little rain!" Mrs. Osler smilingly said: "Oh, you are getting quite smart. I think it is time I was taking you back this afternoon to Oxford, although I believe you would really rather stay here." Dr. Osler acquiesced: "After I have been around those antiques at Oxford for a while I don't know what I should do now and then unless I came down here with the boys."

EDGAR L. GILCREEST, M.D., San Francisco.
University of California.

"THE IMMEDIATE STERILIZATION AND CLOSURE OF CHRONIC INFECTED WOUNDS"

To the Editor:—In his article on the use of zinc chlorid in the sterilization of chronic infected wounds (*THE JOURNAL*, May 8, 1920, p. 1301), Dr. Babcock has treated altogether too briefly the danger in the use of this method, and has not sufficiently emphasized the caustic properties of a saturated solution of zinc chlorid on the walls of blood vessels. It is a powerful caustic reagent, capable of deep penetration, producing an eschar; and if brought in contact with a large artery or vein, as the femoral vessels, may cause a sudden profuse secondary hemorrhage which can be controlled only by ligation. This fact was repeatedly noted among the cases of chronic osteomyelitis of the femur in which operation by this method was performed at Fort McPherson, particularly when the solution was injected under pressure with a syringe.

In August, 1919, this method of introducing zinc chlorid throughout the fistulous tract was practically abandoned for this very reason. I believe it is a mistake to recommend the method to one who does not realize the danger, without making due emphasis on what one may expect. As has been borne out by experience, the patient after operation must be kept under most careful observation even as long as ten days, since instances of severe hemorrhage have occurred many days after operation, attributed by the pathologist to an erosion of the wall of a large vessel due to zinc chlorid.

Another point to be borne in mind is the toxicity of zinc chlorid, as a fraction of a drop injected into the ear vein of a rabbit has resulted in instant death to the animal.

It has occurred to me to write this letter because of the fact that shortly after the publication of this article I saw a case of a chronic osteomyelitis of the head and neck of the femur, and the attending surgeon proposed the injection of zinc chlorid into the sinus according to the method described by Dr. Babcock. The sinus was in the femoral region in very close proximity to the femoral vessels just below Poupart's ligament, and the proposed injection of zinc chlorid under pressure into this sinus would be attended with grave danger of a severe hemorrhage.

CLARENCE H. HYMAN, M.D., Cleveland.

"GAS CYSTS OF THE ABDOMEN"

To the Editor:—Apropos of an editorial entitled "Gas Cysts of the Abdomen" (*THE JOURNAL*, May 15, 1920, p. 1404), I reported such a case in *THE JOURNAL*, Dec. 19, 1919, under the title of "Emphysema of the Cecum." This case also was overlooked by Sloan (*Surg., Gynec. & Obst.* 30:389 [April] 1920) who is referred to in your editorial. His case appears to be the fourth reported in the United States. The first was

by Finney (THE JOURNAL, Oct. 17, 1908, p. 1291), said to be the nineteenth in the literature. The second was by Tunure, *Ann. Surg.* 57:811, 1913, the third by myself and the fourth by Sloan, with excellent remarks on pathology by Karsner. The title, "Diffuse Emphysema of the Intestinal Wall," which is used by Nitch and Shattuck (Proc. Royal Soc., Pathological Section, February, 1920), seems best to describe the condition in all its phases.

E. D. TWYMAN, M.D., Kansas City, Mo.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

RECKLINGHAUSEN'S DISEASE WITH SUPRARENAL INSUFFICIENCY

To the Editor:—In THE JOURNAL, May 22, 1920, is an abstract of an article on the treatment of Recklinghausen's disease with suprarenal extract by Chauffard and Brodin. Would it be possible to inform me how this treatment was carried out, whether 1:1,000 epinephrin was used, and if so whether by mouth or intravenously. I have a case diagnosed as neurofibromatosis in my service and would like to try the suprarenal treatment if I knew more about it.

ARTHUR J. ATTRIDGE, M.D., Providence, R. I.

ANSWER.—The only description of the treatment is that "suprarenal opotherapy was given for a few days in the form of suprarenal tablets (*comprimés surrénaux*). The general condition improved, the blood pressure rose from 15 to 17 (Pachon) and kept at this level on suppression of the treatment." The assumption of suprarenal insufficiency was based on the diffuse bronzing (*melanodermie*); the symmetrical pigmentary patches; the rather symmetrical arrangement of the forty cutaneous or subcutaneous fibromas; the low blood pressure in the apparently vigorous man of 32, and the presence of a large glandular process in the neck, of four years' standing, apparently a tuberculous adenopathy. Chauffard reported in 1896 a case of pigmentary fibromatosis in which both suprarenals were the seat of malignant disease, and Bourcy has since reported a similar case. Oddo and Jullien noted pigmentation of the mucous membranes in three cases of Recklinghausen's disease, and in three cases on record, as in the case here reported, suprarenal treatment was followed by immediate and notable improvement (Pic and Jullien). The writers conclude with the remark that "the fibromatous process may invade the suprarenals, and thus is explained part at least of the symptomatology of Recklinghausen's disease."

ACETYSALICYLIC ACID AND "ASPIRIN BAYER"

To the Editor:—Is the acid acetylsalicylic, advertised by some manufacturers at cheap prices, identical with aspirin, and can it be relied on as an efficient substitute?

C. E. W.

ANSWER.—The following products have been tested and found satisfactory by the Laboratory of the Council on Pharmacy and Chemistry of the American Medical Association, and the products are described in New and Nonofficial Remedies:

- "Acetylsalicylic Acid, Heyden," Heyden Chemical Works.
- "Acetylsalicylic Acid, M. C. W.," Mallinckrodt Chemical Works.
- "Acetylsalicylic Acid, Merck," Merck & Co.
- "Acetylsalicylic Acid (Aspirin) Monsanto," Monsanto Chemical Works.
- "Acetylsalicylic Acid-P. W. R.," Powers-Weightman-Rosengarten Company.
- "Acetylsalicylic Acid-Squibb," Squibb and Sons.
- "Aspirin-L and F," Lehn and Fink.

An examination made in the laboratory two years ago showed that the market supply of acetylsalicylic acid at that time was of equal quality with the German-made "Aspirin Bayer." The inquirer will be interested to learn that the "Aspirin Bayer" now made in America, and exploited with misleading claims in advertising issued by "The Bayer Company," is actually controlled by the Sterling Products Company, which sells "patent medicines," such as cascabels, dandereine, etc.

Utah January and April Examinations

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, Jan. 5-6, 1920. The examination covered 19 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 2 candidates examined, 1 passed and 1 failed. Three candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Number Licensed
John A. Creighton Medical College	(1919)	1
St. Louis College of Phys. and Surgeons	(1918)	1
College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University	(1916)	Illinois
Columbia University	(1918)	New York
Jefferson Medical College	(1873)	Colorado

Dr. Harding also reports the written examination held at Salt Lake City, April 5-6, 1920. Two candidates were examined and passed. Six candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Number Licensed
University of Illinois	(1920)	1
Jefferson Medical College	(1919)	1

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Rush Medical College.....	(1919),	(1920)	Illinois
Kentucky School of Medicine.....	(1906)		Nevada

Connecticut March Examination

Dr. Edwin C. M. Hall, secretary, Connecticut Homeopathic Medical Examining Board, reports the written examination, held at New Haven, March 9, 1920. The examination covered 7 subjects and included 70 questions. An average of 75 per cent. was required to pass. Two candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Minnesota Coll. of Homeo. Med.....	(1905)		86
New York Homeo. Med. Coll. and Flower Hospital..	(1919)		92

Maine March Examination

Dr. Frank W. Searle, secretary of the Maine State Board of Registration in Medicine, reports the written examination held at Portland, March 9-10, 1920. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the three candidates examined, 2 passed and 1 failed. One candidate was licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Harvard University.....	(1918)		83
McGill University.....	(1918)		85

College	FAILED	Year Grad.	Per Cent.

Book Notices

SYPHILIS: A TREATISE ON ETIOLOGY, PATHOLOGY, DIAGNOSIS, PROGNOSIS, PROPHYLAXIS AND TREATMENT. By Henry H. Hazen, A.B., M.D., Professor of Dermatology and Syphilology, Medical Department of Georgetown University. Cloth. Price, \$6. Pp. 647, with 160 illustrations. St. Louis: C. V. Mosby Company, 1919.

The need of "a small book covering the whole field of syphilis in an authoritative way" is stated in the preface. The author and his collaborators are to be congratulated on their success in meeting this need. Dr. Reasoner writes on infection and immunity, Dr. H. A. Fowler on the male genito-urinary tract, Dr. John Dunlop on the bones, joints, muscles, tendons and bursae, Dr. John Lind on the central nervous system, with contributions by Dr. John Hough, Dr. Virginius Dabney on the eye, Dr. L. H. Greene on the ear, Dr. Craig on the Wassermann reaction, Dr. Schamberg on the toxicology and therapeutic testing of arsphenamin, and Dr. Walter van Sweringen on roentgenography in the diagnosis of syphilis. The author also acknowledges his indebtedness to Dr. Edward Hiram Reede in the chapter on affections of the endocrine glands. The material is necessarily presented in brief form. No space is wasted, however, and the excellent bibliography supplies those who would study any part of the subject more extensively. Some important subjects have been given scant attention. Secondary papules on the palms and soles, for instance, certainly deserve more than passing notice. Criteria of cure and differentiation between the various spirochetes might well have been accorded more space. The index, too, could well be made more extensive. Differential diagnosis on the whole is well presented, more thoroughly than in many of the standard books. This makes it a valuable work for the general practitioner. Especially worthy of mention is the discussion of prognosis, treated by Dr. Hazen with common sense and moderation, avoiding the extremes of pessimism and of optimism. The discussion by

Craig of the interpretation of the results of the Wassermann reaction is also to be commended as a sensible presentation of facts which, if applied to the work of the laboratory and the estimation of its value by the clinician, would clear up a great deal of the misunderstanding and false interpretation of that important test. The book presents a great mass of invaluable information in a readable form. It is well printed on good paper, and the illustrations are good.

MANUAL OF OBSTETRICS. By Edward P. Davis, A.M., M.D., F.A.C.S., Professor of Obstetrics in the Jefferson Medical College, Philadelphia. Second edition. Cloth. Price, \$3 net. Pp. 478, with 163 illustrations. Philadelphia: W. B. Saunders Company, 1919.

This is a concise manual of modern obstetrics. In it Davis has covered the subject in a thorough and logical manner, and has brought the subject matter of this second edition well up to date. It can be recommended as a handbook for students and as a reference book for nurses who specialize in obstetric nursing. The print is large and easy to read, the illustrations numerous and clear, and the publication carefully done. One of the few mistakes in proof-reading occurs on page 95 under the caption of the physiology of pregnancy, where Davis says: "If the patient is not well nourished during pregnancy the alkalinity of the blood increases." He doubtless means "decreases." In discussing the diagnosis of pregnancy he states that "the eyes must be noted for signs of exophthalmic goiter," thus giving the impression that the latter condition is a usual accompaniment of pregnancy, whereas it is one of the rare complications. Again, under diagnosis of pregnancy by the roentgen ray, he is vague as to just when in pregnancy the roentgen ray will show the fetal skeleton, and he fails to mention its value near term in recognizing multiple pregnancy. Occasionally a statement is found which is more confusing than helpful, such as: "The presence or absence and the degree of leukocytosis should indicate the power of the patient's resistance and the possibility of infection and suppuration." This quotation, taken from the diagnosis of broad ligament pregnancy, does not in any sense contribute to the diagnosis of the condition under discussion. For the most part, Davis' treatment is based on sound principles and good judgment; however, such advice as: (a) the use of from 1 to 1.5 c.c. of pituitary extract in inertia (p. 222); (b) the use of a sharp spoon curet for interruption of pregnancy (treatment of toxemia of pregnancy); (c) the application of forceps to the breech (forceps), and (d) instructing nurses to give intra-cervical douches in postpartum hemorrhage, is risky if not actually dangerous advice. Still one more statement requires revision, which appears in the description of the technic of the Braxton Hicks version: "The operator observes antiseptic precautions; and if he is accustomed to work with rubber gloves he should use them." There is no *if* in the obstetrics of today!

ORTHOPEDIC AND RECONSTRUCTION SURGERY, INDUSTRIAL AND CIVILIAN. By Fred H. Albee, A.B., M.D., F.A.C.S., Professor and Director of Department of Orthopedic Surgery, New York Post-Graduate Medical School. Cloth. Price, \$11 net. Pp. 1138, with 804 illustrations. Philadelphia: W. B. Saunders Company, 1919.

This book is extensive in its scope, including the ordinary field of orthopedic surgery, with military and much of general surgery of the extremities as a text. It lacks balance in that topics are unevenly discussed. Those in which the author is especially interested and previously contributed, as tuberculosis, are generally given in great detail with much argument in favor of his methods, while others, as osteomyelitis, are incomplete. It is essentially a treatise on therapy, and a commendable feature is that operative methods receive much more attention than is given in other books on orthopedic surgery. The accounts of the author's extensive experience, especially in the field of bone transplanation, are of great importance. Aside from bone repair, the pathology is not well given. Too much space is devoted to arguments in favor of the author's methods and in establishing his priority for various operative procedures. A valuable bibliography is attached to each chapter.

Medicolegal

Liability for False Representations as to Disease

(*Manweiler et al. v. Truman (Ind.)*, 125 N. E. R. 412)

The Appellate Court of Indiana, Division No. 2, affirms a judgment for \$100 damages in favor of plaintiff Truman in this action brought to recover for alleged false representations made to her by the defendants with regard to the nature of the disease with which one of them was suffering. The court says that the plaintiff alleged in her complaint that the defendants came to her home and represented to her that defendant Manweiler was sick with lung fever, and that they had no place where he could be taken care of, and requested her to take him into her house and care for him until he was well enough to be moved; that he was so sick that he could not be taken to a hospital; that he was not ill with a contagious disease; that she told them that she could not take him or care for him if he was sick with a contagious disease; that she relied on the defendants' statement that he was not sick with a contagious disease, and took him into her house; that a short time thereafter she learned that he was so ill with diphtheria that he could not be moved; and that in order to save his life she nursed and cared for him. It was also alleged that when the defendants made these representations to the plaintiff they knew of Manweiler's true condition, and by reason of their false statements caused her to take him into her home. The defendants contended that there was no evidence of intent or design on their part to perpetrate a fraud on the plaintiff; that whatever statements were made by them were made in good faith and based on the statement of a reputable physician. But the question as to whether the defendants falsely represented that Manweiler was sick with lung fever when they knew he was suffering with diphtheria, or whether they acted in good faith with the plaintiff was a question of fact for the jury, and the latter found specifically that the defendants, at the time they took Manweiler to the home of the plaintiff, knew he was suffering with a contagious disease, and that they then knowingly perpetrated a fraud on her. This court cannot set its judgment on the weight of the evidence against that of the jury and the trial judge, and say that there was reversible error on the ground that the verdict was not sustained by sufficient evidence.

Insufficient Evidence of Malpractice—Improper Reference to Insurance Company

(*Sherwood v. Babcock (Mich.)*, 175 N. W. R. 470)

The Supreme Court of Michigan reverses a judgment for \$1,000 damages that was rendered against the defendant for alleged malpractice, and orders that in its stead a judgment be entered for the defendant, notwithstanding that the verdict of the jury was against him. The court says that, in April, the defendant was called to the home of the plaintiff to treat a grandchild of the latter named Edwin Sen, who died on May 16. The case was diagnosed by the defendant as one of pneumonia, but meningitis developed, which was the immediate cause of death. Then a child of the plaintiff, named Irene, became ill, and died on May 30, the cause of her death being reported as typhoid fever. Also, two younger children were taken ill, after Irene, and their illness was diagnosed as typhoid fever, for which they were treated, and from which they recovered, although soon after the death of Irene the defendant was discharged, and another physician was called to take charge of them. The defendant consulted with another physician twice, and with two other physicians once, during the attendance on the family. Three claims of negligence were alleged: (1) Failure of the defendant to segregate the other children from Edwin Sen when he was taken ill; (2) failure to report the illness of Edwin Sen to the health board; (3) and not treating the children for cerebrospinal meningitis. When the other physician was called to take charge of the younger children they were convalescing. The defendant complained that, in spite of the fact that there was no medical testimony supporting the allega-

tions in the plaintiff's declaration, and that all the medical testimony was in direct contradiction of those claims, the case was submitted to the jury and the verdict rendered and judgment entered for the plaintiff. The trial judge seemed to have submitted the case to the jury on the theory that it had a right to gather from the symptoms given by the plaintiff and his wife, which they observed during the illness of the children, coupled with the statement of the second physician that he treated the patients as though they were suffering from meningeal infection, whether or not Edwin Sen had cerebrospinal meningitis, and whether or not the other children were suffering from the same disease. But, from a careful reading of the record, the supreme court is impressed with the fact that the verdict and judgment entered were contrary to the great weight of the evidence in the case. It is impressed with the contention that a judgment should have been entered in favor of the defendant notwithstanding the verdict of the jury, and that error was committed in overruling a motion therefor. A careful reading of the testimony of the second physician showed that it fell far short of furnishing evidence that any of the children had cerebrospinal meningitis. He used the words "possibility," "suspect" and "perhaps." The testimony was too problematic and speculative to warrant the submission of the question to the jury. It gave the jury an opportunity to speculate, and the evidence failed to make a case of malpractice.

The court is also impressed with the contention that it was prejudicial error for counsel for the plaintiff to say, in his argument of the case to the jury, "It is for you, gentlemen, to say whether Dr. Babcock or the insurance company, whose very able attorney is here today. . . ." This language was not only improper, but was reprehensible, and was used without any provocation, there not being a word of testimony in the case with reference to an insurance company.

Rules Relative to Insanity as a Defense to Crime

(*Thomson v. State (Fla.)*, 83 So. R. 291)

The Supreme Court of Florida, in reversing a conviction of murder on the ground that the evidence raised a reasonable doubt as to the defendant's sanity at the time of the homicide, says that when the defense of insanity is relied on, the rule in force in the state of Florida is that if the evidence introduced tends to rebut the presumption of sanity on the part of the accused, and the jury entertains a reasonable doubt, after due consideration of all the evidence as to his sanity, it is their duty to acquit.

The statutory definition of murder, "the unlawful killing of a human being, when perpetrated from a premeditated design to effect the death of the person killed," includes the element of a rational agency, and it devolves on the state to show this as well as any other element of the crime. The law, however, presumes that all men are sane, and, in the absence of evidence indicating a contrary state of mind, both court and jury are justified in acting on this presumption; and when the evidence establishes the criminal act, and indicates nothing as to the mental capacity of the accused to commit the deed, a conviction is not only authorized, but should be had. If, however, there arises from the evidence coming from any quarter a reasonable doubt as to the sanity of the accused, the presumption of law is overcome, and he is entitled to an acquittal, unless the state meets and overcomes this reasonable doubt arising in his favor.

When insanity of a permanent type, or of a continuing nature, or possessed of the characteristics of an habitual or confirmed disorder of the mind, as distinguished from temporary or spasmodic mania, or disorders of mind produced by the violence of disease, is shown to have existed a short time prior to the commission of an act, it is presumed to continue up to the time of the commission of the act, unless this presumption is overcome by competent testimony.

When insanity of the defendant is a real issue in a criminal prosecution, the court should charge the jury that, if the defendant is acquitted on the ground of insanity, the jury should so state in the verdict in order that appropriate action may be taken by the court under Section 3992 of the General Statutes of 1906.

AMERICAN SOCIETY FOR CLINICAL INVESTIGATION

Annual Meeting, held in Atlantic City, N. J., May 3, 1920

(Continued from page 1600)

Certain Phases of the Histamin Problem

DRS. KARL K. KOESSLER and MILTON T. HANKS, Chicago: Perfectly fresh total glands of steers were used. It was found that there is no histamin present in the hypophysis. A typical peptone shock was obtained by the injection of a histamin free peptone; hence peptone shock and histamin shock are not identical. It was found that Witte's peptone—100 gm.—contains the equivalent of 0.00335 gm. of histamin dichlorid.

Basal Metabolism from Birth to Puberty

DR. FRITZ B. TALBOT, Boston: The great interest in basal metabolism is evidenced by the increasing number of reports of the basal metabolism of pathologic conditions. In the past there has been no standard for comparison of infants and children other than the scattered observations of Rubner, Du Bois, Murlin, Howland and a few others. The basal metabolism of normal infants and children has been studied by Benedict and myself during a period of eight years, ending in June, 1919. In this series of investigations were included more than a hundred normal male children and seventy normal female children. In many cases the metabolism of the same child was obtained at different ages. Curves of the total metabolism for twenty-four hours as referred to age and weight, to the metabolism per kilogram referred to both age and weight, and to the metabolism per square meter of body surface referred to both age and weight, may be taken as standards to which may be applied observations on pathologic conditions.

Relation of Sputum Bacteria to Asthma

DR. FRANCIS M. RACKEMANN, Boston: Asthma is a syndrome that may be divided according to its cause into two groups, extrinsic and intrinsic. We are here concerned with those cases of intrinsic asthma in which a focus of bacterial infection in the bronchi is assumed to be the cause. The method of study has been to make intradermal tests with pure vaccines made from organisms isolated on blood agar plates from the patient's sputum, and to institute treatment on the basis of these tests. An early positive skin test was found in one-half hour to consist of an urticarial wheal surrounded by erythema, but late positive tests were found in twenty-four hours to resemble an inflammation. One hundred and twenty-nine organisms were isolated from thirty-nine patients. They included nonhemolytic streptococci, 60 per cent.; hemolytic streptococci, 13 per cent, and staphylococci, 8 per cent. The pneumococcus was found only three times. Twenty-five of this group of thirty-nine patients gave a positive test to one or more vaccines. There were twenty positive tests to an autogenous vaccine and fifteen positives to a heterologous vaccine. In addition to this original group, seventeen patients were tested with only heterologous vaccines, and nine reacted positively. Thus, in the whole group of fifty-six patients, thirty-four, or 67 per cent., gave a positive skin test.

Taking the two groups together, 358 individual intradermal injections were made; 19.5 per cent. of these were classed as positives, which figure includes 7.5 per cent. early positive,

7.2 per cent. late positive, and in addition 4.8 per cent. positive both early and late. With reference to the individual organisms, and considering only those tested on at least five patients, a total of 283 tests were made with thirty-two different vaccines. Fourteen of these thirty-two organisms gave no test at all, and of the four that did give more than two positives, one was a hemolytic streptococcus with three positives, and two were *Staphylococcus albus* with four each. One, a gram negative bacillus, was irritating in that ten positives were obtained in eighteen tests. Treatment with small doses of pure vaccines given at seven-day intervals was carried out in twenty-six patients with results that were in very close accord with the presence or absence of a positive skin test. Of the sixteen patients who were treated with the organism to which they gave a positive test, fourteen were treated successfully. In ten instances this treatment was with an autogenous vaccine. However, ten other patients were treated in the face of a negative test, but with no success at all. The organisms used in treatment, whether successful or unsuccessful, included representatives of each variety found, but were mostly nonhemolytic. These results indicate that the treatment of intrinsic asthma with vaccines is specific.

DISCUSSION

DR. KARL K. KOESSLER, Chicago: Several years ago Dr. Moody and I reported on the results of a bacteriologic study of the aerobic and anaerobic micro-organisms isolated from the bronchial expectoration of patients suffering from bronchial asthma. We emphasized that in the treatment of this disorder by means of bacterial autogenous vaccines, it is essential for obtaining the best therapeutic results to incorporate in the vaccine the anaerobic organisms, together with the common aerobic (streptococci, pneumococci, pneumobacilli, *Micrococcus catarrhalis*, staphylococci, etc.), for the anaerobic bacteria and cocci often show a stronger proteolytic power than the aerobic ones, an activity of fundamental bearing in the production of the bacterial type of asthma. The invasion of the bronchial structure by micro-organisms might produce bronchospasm in a variety of ways. Destruction of the protecting layer of the ciliated epithelium, with losses of substance or minute ulcer formation involving the submucosa, exposes the contracting mechanisms to thermal as well as chemical influences (comparable to similar mechanism underlying pylorospasm and angiospasm). Toxic material formed by micro-organisms in the bronchial structure itself can thus be easily absorbed. But also through the blood and lymph way, toxic substances of the type of histamin can be absorbed even from distant foci of infection, associated invariably with protein destruction, substances which produce a marked spastic contraction of the smooth muscle fiber system of the bronchial structure. We thus believe that a large number of cases of bronchial asthma are the result of amin formation and amin absorption, and belong to a group of disorders for which we might use the term "aminosis."

Further Studies on Active Immunization Against Pneumococcus Pneumonia in Monkeys

DR. RUSSELL L. CECIL, New York: Small doses of pneumococcus Type I saline vaccine, administered subcutaneously, do not confer complete immunity against a subsequent pneumococcus Type I pneumonia, although they do modify favorably the course of the disease. Three large subcutaneous injections of vaccine (20, 40 and 60 billion, respectively) given at intervals of one week cause very little reaction in the monkey, and are sufficient to prevent infection altogether. Small doses of pneumococcus vaccine will also produce an adequate immunity, if given intravenously. Small doses of living virulent sensitized pneumococci, when injected subcutaneously, may give rise to a temporary pneumococcus bacteremia, from which the monkey recovers. Monkeys vaccinated with the sensitized culture of pneumococcus failed to develop pneumonia when injected intratracheally with living virulent pneumococci. At necropsy, however, two of the monkeys in this series showed small multiple abscesses in the lungs. These experiments afford a rational basis for prophylactic vaccination against pneumonia in man. It is true

that the dose of vaccine employed in these experiments was larger than that which is usually administered to man; but on the other hand, it must be emphasized that the monkeys received five or six hundred virulent pneumococci directly into the trachea, while in the case of man, pneumonia is probably induced by a much smaller number of micro-organisms.

Effect of Salicylates on Formation of Immune Bodies

DR. HOMER F. SWIFT, New York: The known action of salicylates is as an antipyretic and an analgesic in concentrations that can be safely administered. In strong concentrations it is also antiseptic; but in the concentrations in which it is present in the body, it is considered as having no antiseptic action. Whether it exerts an antibacterial action in the body in therapeutic concentrations is as yet not established. In addition to the above mentioned actions which are exerted in many diseases, in rheumatic fever it has apparently a true antiphlogistic action, as shown by the rapid recession of the various signs of acute inflammation about the affected joints, following its administration in sufficient doses, as well as by the arresting of the spread of the affection to other joints. It is evident, however, that the course of the general infection is not shortened, nor are the cardiac complications prevented by the drug. Consequently, it seemed of interest to determine the exact influence of salicylates on the development of immunity. The averages of several animals showed that the group that received salicylates had a lower antibody formation than the untreated controls. The difference was more marked in those experiments in which the antigen was given in small amounts with a correspondingly low concentration of antibodies in the entire group. The same general result was found with all three types of antibodies studied. An effort was then made to determine the mechanism of this depression in the formation of antibodies. The salicyl-treated animals showed no greater loss in weight or appetite, nor more marked depression in the condition of the salicyl-treated animals than in the controls. When the bacteria were given in the living state, the febrile response was as great in the salicyl-treated animals as in the controls. The effect of exposure of antigen to solutions of sodium salicylate in vitro and subsequent injection of the salicylated bacteria or red blood cells pointed to the depression's being due to a direct action of the salicyl on the antigen. In two series of experiments, untreated controls showed the highest antibody curve; the next highest was shown by the animals that received salicylates by mouth and antigen intravenously, and the lowest by the animals that were immunized with salicylated antigen. Marjorie Cook has lately shown that the formation of antibody is dependent on the rate of absorption of the antigen. Reasoning by analogy of effect, it is suggested that the depression of antibody formation may be due to a decreased rate of absorption of the antigen in salicyl-treated animals. It is also suggested that the antiphlogistic effect may be due to a depression of the irritative properties of the etiologic agent in rheumatic fever.

"Acute Dilatation of the Heart," So-Called, Occurring During or Following Surgical Operations; Its Mechanism and Management

DR. SAMUEL A. LEVINE, Boston: Sudden cardiac upsets were observed in nine surgical patients at the Peter Bent Brigham Hospital. The condition was called acute dilatation of the heart in some cases, and might well have been similarly diagnosed in the others had not the true nature of the disorder been discovered. "Acute dilatation of the heart" has been used as a medical waste-basket; whenever possible (as happened in all of the cases taken up here) a more definite and well understood name should be given to the condition. The upsets all occurred suddenly and unexpectedly; three while the patients were under ether anesthesia (one before the actual operation had started, one during the operation and one just after it had been completed), and the other six during surgical convalescence, from one to nine days after the operation. The attacks varied in severity from being entirely unobserved by the patient to complete collapse, with cessation of breathing, cyanosis and danger of impending death. The duration of the attacks was from several minutes

to several days. How long those attacks that were deliberately arrested by medical procedures would have lasted it is difficult to tell. Electrocardiograms of six of the patients were taken during the upset, and the clinical course of the other three left no doubt as to the diagnosis. Three were found to be due to paroxysmal auricular tachycardia, four to paroxysmal auricular fibrillation, and two to paroxysmal auricular flutter. All but two were transient in nature. The three cases of paroxysmal auricular tachycardia occurred while the patients were under ether anesthesia, and in each instance the attack ended either by direct vagal pressure over the carotid artery or by ocular pressure. One of them went into collapse on the operating table, stopped breathing, the heart rate suddenly jumped to 216, and the life of the patient seemed to be in imminent danger. Left vagal pressure brought the attack suddenly to an end. The proper administration of digitalis controlled the heart's action in the cases of paroxysmal auricular fibrillation and flutter.

In reviewing these nine cases, no constant etiologic factor could be found. It seems impossible to predict what type of surgical patient will have a paroxysmal cardiac upset, and very likely some of these patients would have had similar paroxysms at some future date even if they had not been subjected to operations. Roentgen-ray studies of the size of the heart could not be made during these attacks, but others in the medical wards have had roentgenograms taken during and after similar attacks without showing any appreciable dilatation, except in a very rare instance. It is important to appreciate that "acute dilatation of the heart" is a medical diagnosis which rests on very insecure ground, and that wherever possible, careful observations of the mechanism of the heart beat should be made, in the hope of accurately describing the condition and instituting the proper treatment.

The Enzymes of Pneumococcus

DRS. O. T. AVERY and G. E. CULLEN, New York: In the study of the enzymes of pneumococcus, use has been made of the fact that pneumococci rapidly undergo solution in the presence of bile. By dissolving the organisms in bile and testing the cell-free solution on suitable substrates, enzymes are readily demonstrable. These enzymes possess the power of actively hydrolyzing peptones to simpler peptides and amino acids; of converting carbohydrates into simpler products, and of splitting esters into fatty acids. In demonstrating carbohydrate cleavage, however, bile was found to inhibit completely the hydrolysis of sucrose and starch, so that a different method of preparing the enzyme solution was necessary. For this purpose it was found that the organisms suspended in tenth molar phosphate solution of pH 6.2 undergo disintegration quickly with the release of intracellular substances capable of actively hydrolyzing carbohydrates. By the methods described it is possible to prepare enzyme solutions which are sterile and by bacteriologic technic to maintain sterility throughout the experiment, without the use of antiseptics.

Evidence is presented that these enzymes exist preformed within the bacterial cell and are therefore of the type known as endo-enzymes. The proteolytic enzymes exhibit greatest activity in the further hydrolysis of the intermediate products of protein digestion, such as peptones. From 30 to 40 per cent. of the available peptid-nitrogen in peptone substrates is split to amino nitrogen. This fact, together with the observation that the zone of its optimal activity is pH 7.8, indicates that this enzyme is erepsin-like in character. The curve of its activity rapidly falls with increasing acidity, until at a pH of 4.5 complete inhibition results. The proteolytic enzyme is sensitive to heat; an exposure of ten minutes at 100 C. destroys its activity. Dissolved in ox-bile, the enzyme retains about 40 per cent. of its activity over a period of six weeks.

By similar methods the fact has been established that within the pneumococcus cell there exists a remarkably active lipase; the acid formed by its action on 2 per cent. tributyrin representing a normality of about twentieth normal butyric acid. The maximum activity of the intracellular lipase occurs at a reaction of pH 7.8, and progressively decreases with increasing acidity of the substrate. The optimal reaction corresponds closely with that of the endopeptonase, and

both coincide with the optimum hydrogen ion concentration for growth of pneumococcus. It has been found that loss of virulence is not associated with a corresponding loss of either erepsin or lipase activity.

In germ-free filtrates of broth cultures of pneumococcus, enzymes are found free in solution only when growth has progressed to the phase in which cell disintegration begins and liberation of the intracellular substances into the culture medium occurs. During the early stages of growth of pneumococcus when, under optimal cultural conditions, organisms are multiplying at their maximum rate, and little or no cell death is occurring, enzymes cannot be detected in culture filtrates.

The inhibiting action of bile on the activity of the carbohydrates, splitting enzymes of pneumococcus is overcome by effecting cytolysis of the bacterial cells in phosphate solution at pH 6.2. Alternate freezing and thawing of the bacterial suspension greatly facilitates rupture of the cell membrane and liberation of the intracellular substances. In this manner it has been demonstrated that there exist intracellular enzymes capable of converting sucrose into monosaccharids (invertase), of splitting starch through the dextrin to reducing sugars (amylase), and of hydrolyzing inulin (inulinase). The zone of hydrogen ion concentration in which these enzymes are active bears a striking correlation to the biologic activity of the living cell.

In addition, certain other active intracellular enzymes are present in solutions of pneumococcus bodies. These, in brief, are in the nature of bacteriolytic enzymes capable of causing complete and rapid dissolution of heat-killed bacteria.

Effect of Experimental Lesions of Branches of Bundle of His on Form of the Electrocardiogram

DRS. FRANK N. WILSON and GEORGE R. HERRMANN, St. Louis: In a dog attempt was made to cut the left branch of the bundle of His by thrusting a small tenotomy knife through the wall of the left ventricle and pressing the cutting edge against the septum. The characteristic ventricular complexes of left bundle-branch block appeared at once and were recorded. They persisted only a few minutes, however, giving place to complexes of the normal type. Right bundle-branch block was then produced by thrusting the knife through the wall of the right ventricle and pressing on the septum with the noncutting edge. Characteristic ventricular complexes appeared at once and persisted for about one and a half hours. At the end of this time, complexes of normal type again returned. The dog was killed, the heart was opened, and drawings were made of the branches of the bundle of His and the lesions produced. From a comparison of the lesions produced with the electrocardiograms recorded, we confirmed the belief that lesions of the two chief branches of the bundle of His are accompanied by characteristic electrocardiograms. Lesions of the subdivisions of these branches did not in our experiments produce more than minor changes in the form of the electrocardiogram.

Virulence of Streptococci and Hemolysin Production.

DRS. WARFIELD T. LONGCOPE, F. A. STEVENS and J. W. S. BRADY, New York: The relation between virulence and hemolysin production has been a subject for much controversy because uniform methods have not been used by different workers. The fact that the concentration of hemolysin varies during the growth of a broth culture of streptococcus has been recognized but not applied to the estimation of the minimum hemolytic unit. To determine the point at which the concentration is greatest, hourly hemolysin tests must be made. All other factors except the invasive power of the organism must be constant. The estimation of virulence cannot be based entirely on clinical evidence because of the variations in individuals and in the conditions under which infection takes place.

Strains of beta type streptococcus, from blood cultures or empyeme exudates, *Streptococcus pyogenes* on sugar fermentation (Holman), were passed through mice until the virulence was increased from twenty to thirty times. Equal numbers of living bacteria, in the virulent and avirulent forms of the same strain, were then seeded in flasks of 20 per cent. horse serum broth. At seeding, all factors in the two flasks

were similar in every respect. Curves of growth and hemolysin were made, and it was found that in tests with a 5 per cent. suspension of mouse cells in physiologic sodium chlorid solution, both the virulent and avirulent strains produced equal, maximum hemolysin concentrations. Under these conditions, virulence does not influence streptolysin concentration.

Methyl Alcohol Poisoning

DRS. WALTER W. PALMER and GEORGE A. HARROP, JR., Baltimore: In a case of acute methyl alcohol poisoning, it was found that the patient was suffering from a severe acidosis, associated with a marked rise in the excretion of organic acids in the urine, two of which, lactic and formic, were recovered in considerable amounts. We have undertaken further study of this condition experimentally, using dogs. The dosage of methyl alcohol by mouth which will terminate fatally in a day or two if untreated can be determined fairly closely, and is about 12 c.c. per kilogram. On the other hand, such acute death has occurred in but one instance (an animal in bad condition, suffering from severe mange), in which the dosage has not exceeded 10 c.c. per kilogram.

An acidosis has been produced by the administration by stomach tube of amounts of methyl alcohol in excess of 6 c.c. per kilogram. The serum bicarbonate content has ranged between 35 and 20 per cent. by volume. Outspoken dyspnea is not regularly produced—in fact, in the fatal cases death appears to be from respiratory paralysis, the respirations gradually lessening in number. In one animal, observed during two hours before death, the visible respirations did not exceed two or three a minute. The acidosis appears in from twelve to thirty-six hours after the injection of the alcohol, and is associated with a marked rise in the urinary ammonia and in the excretion of organic acids, the amount for twenty-four hours rising from the normal of about 20 c.c. of tenth normal acid per kilogram to from 100 to 150 c.c. per kilogram. As is well known from the work of Pohl, there is a great increase in the excretion of formic acid, which begins, however, somewhat after the first rise in the curve of organic acid excretion. The excretion of formic acid has not accounted for more than 60 per cent. of the total increased organic acid excretion, and in two completed experiments it averages from 20 to 50 per cent. of the latter. The increase in acetone bodies is not much more than can be accounted for by starvation.

We have studied the excretion of methyl alcohol into the stomach. It appears after intravenous injections and was recovered immediately after an injection of as small an amount as 2 c.c. per kilogram. When given by mouth, it has been possible even after twenty-four hours to recover by repeated lavage as much as 10 per cent. of the amount administered. There is no doubt that an active secretion of methyl alcohol into the stomach does occur, and that repeated and thorough lavage over a period of several days is urgently indicated. Small amounts have been recovered as late as the seventh day. Besides removing appreciable quantities of the alcohol, there is less tendency in dogs thus treated to have gastric hemorrhage and bloody diarrhea.

The mechanism of methyl alcohol poisoning is quite unknown except for several isolated facts: It is distributed in approximately equal concentration throughout the body; it is catabolized very slowly with the formation and excretion of formic acid, and it is itself excreted by the lungs and in the urine. Methyl alcohol is known to be less acutely toxic than ethyl alcohol. It therefore seems likely that some other intermediary oxidation product may play a rôle. Such a product is formic aldehyd. We have found traces of formic aldehyd in the blood serum, urine, spinal fluid and aqueous humor of dogs poisoned with methyl alcohol. It is present, it is true, in very small quantities, but the effect of its constant formation in the body over a period of days has not been studied. We do not believe the effect of the injection of doses small enough to be tolerated—and they have to be very small—is a phenomenon comparable with this continuous production over a period of days. Investigation of the part played by this substance and quantitative studies of its formation and excretion are contemplated.

Primary Carcinoma of Duodenum.—In the case cited by Deaver and Ravdin the tumor was situated at the terminal end of the second portion of the duodenum. There was no obstruction of the common bile duct, nor evidence of obstruction of the pancreatic ducts, nor other evidence of metastasis. It is believed that this was a case of primary duodenal carcinoma, although the history was very similar to that of ulcer. The rapid loss of weight and the rather short duration of the disease (seven months) on the other hand, would point to primary carcinoma. Carcinoma of the duodenum is found in 0.033 per cent. of hospital necropsies.

Cure of Hookworm Infection.—This paper is based on 231 cases, all of which were observed twenty-nine days or over (up to 228 days in one instance), and no case is reported as a cure that did not show an average of from ten to fifteen consecutive negative stools during a period of four weeks after treatment. The five-stool method of examination was resorted to in each instance. The usual mouth treatment was not very encouraging in its results. Much more efficient results can be obtained by the method of intra-intestinal tube treatment, owing to the fact that the full, concentrated dose of vermifuge is delivered precisely at the point of infection. Instead of 34 per cent. of cures, as in the case of a first mouth treatment, fully 80 per cent. are cured by a first tube treatment. Only one repetition is necessary for the relief of the great majority of infections.

Direct Treatment of Catarrhal Jaundice.—The treatment used by Lyon was as follows: All patients, whether with bronchial conditions or otherwise, were cautioned repeatedly against the swallowing of saliva; noses were sprayed with Dobell's solution; throats gargled with strong potassium permanganate solution, 1 grain to the ounce. A sterile duodenal tube was passed to the stomach in the fasting morning state, the residuum withdrawn for analysis and microscopy, with a sterile individual syringe for each patient. The stomach was washed with water, followed by liquor antisepticus alkalinus (in the hyperacid cases) or hydrochloric acid solutions (in the subacid cases), then water again until the washings were clear. Then 250 c.c. of solution, one day, of potassium permanganate (starting with 1 to 15,000 and increasing to 1 to 8,000 and the next day a solution of silver nitrate (1 to 20,000 to 1 to 10,000) was introduced into the stomach, allowed to remain there three to five minutes, and as much as possible syringed out. The patient was then given a glass of water to drink, turned on the right side and by slow swallowing the tube was allowed to enter the duodenum. When this was reached (in from

fifteen to forty-five minutes) the duodenal contents were aspirated for study. In all these cases the duodenum was at first found to be bile-free. After the duodenal contents had been aspirated for study Lyon introduces through the tube 50 to 100 c.c. of 25 per cent. saturated solution of magnesium sulphate and bathes or douches the duodenal mucosa. This is again followed by aspiration.

Treatment of Hypertension.—The diet which Moschcowitz orders for these patients is, in many respects, similar to that of a case of diabetes of fair tolerance. The diet consists principally of fruit, coffee or tea (without sugar), meat, green vegetables, salad, cheese and a limited quantity of bread. In other respects the quantity is not limited. Moschcowitz believes in gradual exercise. The ideal form of exercise for patients with hypertension is golf. If a sport cannot be undertaken, walking provides an excellent means of exercise. If for one reason or another even walking is not possible, systematic brisk massage will serve up to a certain point as a tolerable substitute for exercise. The patient's improvement may be decided, not by a decrease in systolic pressure but by a decrease in diastolic pressure and consequent rise in pulse pressure. Attempts to reduce the blood pressure by direct methods are futile. Drugs reduce blood pressure, but their effect is evanescent and no permanent gain is ever derived. The use of digitalis, nitrites, iodids, caffeine and chloral hydrate in selected cases is discussed.

Antisyphilitic Treatment of Aortic Aneurysm.—Three cases of aneurysm of the thoracic aorta of syphilitic origin are reported by MacLachlan. Two were of massive size. Special emphasis is placed on the value of medicinal treatment of these cases. Iodids, mercury and arsphenamin in addition to the usual hygienic measures yielded excellent results in these cases.

Significance of Xanthochromia.—In acute or subacute conditions, Nammack says, the presence of yellow spinal fluid strongly suggests the probable diagnosis of tuberculous meningitis or poliomyelitis.

Mushroom Poisoning.—The five cases reported by Alexander occurred in one family. A mild nephritis and a renal glycosuria were the persistent and predominating features.

Pulmonary Form of Paratyphoid Fever.—Four of six cases of paratyphoid fever studied by Klein and Torrey have been associated with severe pulmonary disturbances. There seems to be a definite pulmonary form of paratyphoid fever which may be easily mistaken for any of the acute respiratory infections. The pulmonary symptoms and findings often precede any intestinal manifestations. Of the pulmonary complications, bronchopneumonia is the most alarming. The bacilli are found in the sputum. The bacilli have also been isolated from the purulent discharges of a chronic purulent otitis media, caused by other infections previous to the paratyphoid disease and from the secretions of pyorrhea alveolaris.

Purpura from Serum Disease.—The case of purpura reported by Meleney occurred during the course of serum disease following the use of antipneumococcus I horse serum in pneumonia. The elements of blood coagulation were normal, and it is therefore probable that the purpura was due to the presence of a toxin associated with the attempt of the body to eliminate the foreign protein. The evidence points to the capillary walls as the site of the lesion.

Treatment of Gonorrhea in Women.—Santal oil, in 10 minim doses, three times daily, and a urinary sedative containing 5 minims of tincture of hyoscyamus and 10 grains of sodium bromid to 1 dram of the liquor of potassium citrate, every three hours, are used by Block in the treatment of the acute urethritis of gonorrhea. A 15 per cent. solution of silver nucleinate or a 5 per cent. solution of silver nitrate, is applied to the entire length of the urethra. In the presence of a gonorrheal discharge from the cervix, hot douches of 1:8,000 potassium permanganate solution are taken four or five times daily. As soon as the discharge is well under control, which ordinarily occurs in about two weeks, local treatments to the cervical canal are given. In applying any medicated solution to the cervical canal one of the most

important points that must be observed is that the canal should be cleansed thoroughly and dried in order that the medicament may come into actual contact with the infecting organisms which lie in the cervical glands. Block wipes away the major portion of the discharge and then thoroughly sprays the cervix with an alkaline solution, in order to dissolve the mucus. The cervix is again dried and then an applicator soaked in an alkaline solution (liquor antisepticus alkalinus) is passed into the canal as far as the internal os and moved to and fro, after which a dry cotton swab is passed into the canal and thin discharge removed. This process is repeated several times until all of the mucus is removed and the canal is left clean and dry. A 10 or 12.5 per cent. solution of silver nitrate is vigorously applied to the canal as far as the internal os, and immediately afterward tincture of iodine is similarly applied. Following this application the cervix and culdesac are thoroughly dried and the speculum withdrawn. Only in very exceptional cases is a tampon inserted.

Bactericidal Value of Potassium Mercuric Iodid.—The experiments reported on by Macfarlan show that potassium mercuric iodid is a powerful germicide exhibiting marked bactericidal efficiency in high dilutions. Organic matter diminishes its potency to a relatively slight degree. These facts, taken in consideration with its great solubility, its freedom from irritant action and its comparatively low toxicity in the solutions efficacious for germicidal purposes, would seem to recommend this double salt of the iodids of potassium and mercury as the most desirable of the inorganic germicides.

Effect of Subcutaneous Injection of Epinephrin.—Forty-six experiments are reported by Sandiford on the effect of the subcutaneous injection of epinephrin chlorid on the metabolic rate, pulse rate, and blood pressure of patients suffering from various disorders of the ductless glands. A supplementary series of twenty-seven experiments is added in which a study was made of the effect of the epinephrin injection on the pulse rate, and blood pressure (the basal metabolic rate being known). Epinephrin chlorid (0.5 c.c. of 1:1,000) injected subcutaneously invariably causes an increase in the metabolic rate. This increase is usually

accompanied by an increase in the ventilation rate, respiration rate, number of heart beats each minute, volume of each beat, greater utilization of the blood carrying power and peripheral dilatation with an increased systolic and decreased diastolic blood pressure. No relationship was found between the intensity of the epinephrin reaction and the degree of hyperthyroidism and hypothyroidism. Attention is directed to the similarity of the metabolic rate curve following the injection of adrenalin to that found by Lusk from a carbohydrate plethora and to the possibility that the increased heat production is due to an excess of carbohydrate metabolites. It is suggested that in addition there may be a direct stimulation of cellular combustion.

Effect of Feeding Carbohydrates on Pancreas.—In general, Jensen and Carlson's results support the view that a liberal carbohydrate diet tends to change diabetes levis into diabetes gravis, after partial pancreatectomy in dogs. But their experiments do not constitute a clear demonstration of this thesis, in fact they are not much more conclusive than the experiments reported earlier by Thiroloix, and by Allen.

Renal Activity and Acid Base Equilibrium.—The urea excreting activity of the kidney under strain was measured by Nagayama after the administration of a mixture of acid and alkaline phosphate of neutral reaction, and also after the administration of an amount of acid phosphate containing the same amount of phosphorus. A distinct decrease in function was observed after acid phosphate. Since the only essential difference in the conditions of these experiments lay in the fact that after the neutral phosphate mixture the acid base equilibrium remained unchanged, whereas after acid phosphate there was a shift toward the acid side, it is concluded that the decrease in the alkalinity of the plasma induced by an increase in the amount of acid phosphate within the body, decreases the urea excreting activity of the kidney. The administration of an amount of alkaline phosphate containing an amount of phosphorus equivalent to that given in the experiments with neutral and acid phosphates, only slightly increased the alkalinity of the plasma and had no appreciable effect on renal function. The administration of amounts of sodium bicarbonate which markedly increased in alkalinity of the plasma was accompanied by a slight decrease in the urea excreting activity of the kidney. Nagayama claims that the urea excreting activity of the kidney measured during the strain is put on the excretory capacity by the simultaneous administration of a neutral mixture of acid and alkaline phosphate.

Physiologic Response to Pituitary Ingestion.—In four out of six individuals, studied by the authors, the ingestion of the pituitary substance caused an increase in the uric acid concentration of the blood. This is interpreted as being probably due to a decreased kidney permeability brought about by the administration of the drug.

- Acrodermatitis Chronica Atrophicans; Report of Case. M. Scholtz, Los Angeles.—p. 565.

Congenital Syphilis.—The case reported by Fraser is one more to be added to those of apparently nonsyphilitic and immune mothers bearing children that have been proved syphilitic. From a review of antenatal pathology and embryology and the morphologic evidence in this case it would appear that infection takes place only after the fetal organs have been formed—a fact which excludes the theory of germinal transmission unless a practically unsupported theory of "larval inactivity" of the infecting organism is assumed. From the facts reviewed the most plausible explanation of the 5 per cent. residue of nonsyphilitic and immune mothers of syphilitic children is that these mothers have a mild, low grade form of syphilis.

Purpura Annularis Telangiectodes.—The cases reported by Weiss present the following deviations from the cases reported by other observers: There is very intensive, dark brown pigmentation over the middle of the legs, with whitish achromia in the center. There are almost numberless discrete lesions, with the yellowish discoloration in the area of the fading spots, which discoloration is not due to pigment deposit, but to a degeneration of the connective and elastic tissues. The evolution and the involution of the lesions and all their stages are observable simultaneously (coexistence of lesions). A slight raising above the level of the skin is present, independently of the keratotic follicles. The coil glands show evidence of a cloudy swelling and some degeneration, while the follicles are not involved. Lesions appear at the site of a biopsy, which lesions in every respect are similar to the original ones. This fact shows almost to a certainty a vasomotor trophic influence on the peripheral vessels.

- *Influence of Roentgen Ray on Progress of Tuberculosis. J. A. Weinberg, Omaha.—p. 565.

Experimental Pellagra.—Goldberger and Wheeler report briefly the results of an experiment carried out at the Rankin Farm of the Mississippi Penitentiary to test the possibility of producing pellagra in previously healthy men by feeding a monotonous, principally cereal, diet. They believe that the conclusion seems warranted that pellagra developed as the result of the diet.

Electrocardiogram Studies.—The study made by Willius comprises 747 cases and covers a period of five and one-half years. The cases were divided into two major groups, cases (550) with Q R S complexes definitely notched, and cases (197) with slurring or localized thickening of the ascending or descending limb, or both. Both groups were subdivided according to derivation occurrence.

Influence of Roentgen Ray on Tuberculosis.—Weinberg attempted to hasten the progress of infection in guinea-pigs following tuberculous inoculation by exposing the animals to massive doses of the roentgen ray. In the first and second series of guinea-pigs there was no apparent difference in time of appearance of the tuberculous lesions in the roentgenized animals and the controls. In the third series, there was a difference of a few days in the time of death, the average time of death occurring two days earlier in the roentgenized animals than in the controls. This series received two roentgen-ray exposures. The fourth series showed the same difference in time of death between the roentgenized and the control animals, as was observed in the third series. The leukocytes of the blood stream are markedly reduced in number by exposure to the roentgen ray. The reduction is proportionate to the length of exposure with a given current and voltage. The lymphocytes are most markedly affected.

Voluntary Acceleration of Pulse Rate.—Cargile cites the case of a woman, aged 42, who possessed the rare power of voluntarily accelerating her pulse rate to an unusual degree. She does not know how she does it, except by intense desire and mental concentration. The acceleration begins very

promptly and sometimes cannot be maintained long, because it is very fatiguing. In thirty seconds the rate is increased over forty-five beats, and two minutes after the command it is about 168 beats per minute, instead of eighty-two.

Multiple Primary Tumors.—One of Blair's patients had a melanosa sarcoma of the mediastinum, with a primary carcinoma of the esophagus. In the apices of both lungs were found extensive adhesions and evidences of old consolidations. The liver was enlarged but no nodulations or tumor formations were present. There were chains of enlarged glands in both supraclavicular triangles, more marked on the right side. These glands varied in size up to 1 cm. in length and were mostly of a deep black color. Both axillae contained numerous chains of glands accompanying the vessels, those of the left axilla being much larger. On the left side of the trachea, about the level of the arch and slightly compressing it, was a large tumor mass, 3 cm. in length, and 2 cm. in diameter. This mass was without pigmentation. Esophagus: atypical squamous celled carcinoma, occupied the middle of the lower thirds of the esophagus about 10 cm. in length, extending through all the coats of the esophagus and almost obliterating the lumen, with metastases in the paravertebral glands. The remaining parts of the body were remarkably free from the metastases, a few melanosa sarcomas being found in the left kidney and suprarenal. The nevus was examined but did not show any carcinomatous proliferation. A second patient had a carcinoma of the ileum and an adenocarcinoma of the appendix. The third patient had a carcinoma of the stomach and gastric lymph nodes with metastases to the vertebrae and a mixed tumor of the ovary.

Intravenous Serum Therapy of Typhoid.—Adelung reports on twenty cases of typhoid treated by intravenous injections of polyvalent sensitized typhoid vaccine as prepared by F. P. Gay. The same vaccine was also used subcutaneously for the purpose of immunizing against relapse, but is not included in this report. The vaccine was given intravenously in doses varying from 75 million suspended organisms (0.25 c.c. in volume) to 525 million suspended bacilli (1.75 c.c. in volume), most commonly at two or three day intervals, though many of the intervals were much longer. The impression was gained that the vaccine is most effective when given at the shorter intervals—two or three days. But it is apparent that the proper guide is the course of the fever curve, and not any fixed rule. In this series of twenty cases, nine-one intravenous injections were given, always with Gay's vaccine. Condensed chemical reports are given.

Ethmoid Malignancy.—One of Jordan's patients had a carcinoma; the other had a sarcoma of the ethmoid.

Achyilia Gastrica.—Best gives his patients 10 per cent. hydrochloric acid with instructions to take from 20 to 30 drops in a glass of water during each meal. An alkaline mouth wash is used immediately after eating. But maintains that it is physiologically correct to take the acid in this way—in sips or swallows—rather than at one time, as is usually done.

Histogenesis of Carcinoma in Pancreas.—In the microscopic examination of sections of the pancreas from the 262 cases that were selected by Horgan for this study, hypertrophy of the islets in connection with a chronic pancreatitis was found in forty-eight cases. None of the patients showed glycosuria in any of the urinalyses of twenty-four hour specimens made while under observation and examination; 79.3 per cent. were found to be cases in which a gastric or duodenal ulcer was found at operation or at necropsy. In the series of 262 cases gastric ulcer was found in seventy-one; in seventeen the islets showed hypertrophy. Duodenal ulcer was found in sixty-one cases; in nineteen the islets showed hypertrophy. Gastric and duodenal ulcer were found associated in eleven cases; in two the islets showed hypertrophy. Hypertrophy of the islets was also observed in six cases of gastric carcinoma, two cases of carcinoma of the rectum, one case of carcinoma of the sigmoid, and one case of cyst of the pancreas. Hypertrophy of the islets was observed grossly and in section from all portions of the gland.

Effects of Heavy Metals on Proteins.—From his observations, Kehoe concludes that if the toxicity of the heavy metal salts is due to the coagulation of the proteins of the body, and if such coagulated proteins may be restored to their former state by the introduction into the body of proper salts and alkalies, the primary toxic effects of the heavy metal salts may be combatted intelligently.

Tuberculosis Complement Fixation Tests.—Positive fixations were obtained by Stivelman in 24 per cent. of 108 nontuberculous individuals. Of 592 serums from definitely tuberculous individuals, 310, or 52.4 per cent., gave a positive reaction, and 282, or 47.6 per cent., gave a negative reaction. Of these 282 patients, 176 had a positive sputum. Of the 294 cases, a positive reaction was obtained in 178, or 60.5 per cent., while of the 298 inactive cases, 132, or 44.3 per cent., reacted positively. Of 108 patients who had pulmonary hemorrhages subsequent to admission, forty-three had a negative fixation and sixty-five a positive fixation. Among the 700 serums tested, eleven reacted strongly positive to the Wassermann test, or an incidence of syphilis of 1.6 per cent. Four of these patients had a positive sputum and a negative tuberculosis fixation test and clinical evidence pointed to the coexistence of both diseases. Four were nontuberculous and gave a negative tuberculosis fixation. One was nontuberculous but reacted positively to the tuberculosis deviation test.

- *Deep Localization in the Cerebral Cortex. E. G. Van't Hoog, Amsterdam.—p. 313.
- *Multiple Brain Abscesses Secondary to Bronchiectasis and Kyphoscoliosis. C. C. Saehof, Chicago.—p. 330.

Deep Localization in Cerebral Cortex.—The results of Hoog's investigations show that the supragranular cortex layers are receptory associative, in accordance with Ariens Kapper's functional deviation, and that the functional nature of the granules is also receptive and associative in the post-central region. The granular cells should, moreover, be conceived of as matrix cells not only in the fascia dentata but also in the neocortex.

Multiple Brain Abscesses Secondary to Bronchiectasis.—Saehof reports a case of multiple bilateral brain abscesses secondary to bronchiectasis caused by the wedging of the lower lobe of the right lung into a pocket formed by a hyphoscoliosis. The causative agents isolated and cultivated from both the abscesses and the suppurating lung were *B. fusiformis* and anaerobic streptococci. The infection evidently traveled through the blood stream.

Operation for Irreducible Paralytic Dislocation of Hip Joint.—Jones has enlarged the acetabulum, according to Albee's method. In these cases before operation the luxation could be reduced and created at will. The operation included reefing the capsule, and was followed by plaster fixation for from three to five months. Sufficient muscle activity was present to give a good functional hip joint without ankylosis and with excellent stability.

New Protozoon of Man.—A small biflagellated protozoon was found by Wight and Lucke in the direct smears and in cultures from three postmortems of patients dead from acute influenza. They occurred, respectively, in the heart's blood, sphenoidal sinus and the lung, and apparently produced no tissue changes. The organisms were round or pear shaped, possessed two free flagella and a kinetonucleus. They were easily cultivated on rabbit's blood glycerin agar. The authors regard these organisms as accidental invaders, possibly belonging to the genus Prowazekia.

Study of Irritating Skin Vapors.—An apparatus is described by Eyster and Maver by means of which the skin or mucous membranes may be exposed to accurately controlled concentrations of toxic vapors under conditions simulating the presence of such vapors free in the atmosphere. Data are included on the skin toxicity of dichlorethylsulphid on rabbits and on man and on the toxicity of the vapors of the rabbit's eye, in order to illustrate the method of use and applicability of the apparatus. The data suggests the necessity of determinations on man when human toxicity determination is desired in the study of other irritant vapors.

Anesthetic Properties of Phenylmethyl Carbinol.—According to Hjort and Kaufmann *dl* phenylmethyl carbinol is a more potent local anesthetic on the rabbit's cornea and in the human skin than either its isomer rose oil or their homologue benzyl alcohol, but not in proportion to its greater toxic action. The relative instability of the α -phenethylol offers further objection to its practical application. It is suggested that the increased physiologic action may be due to the presence of the asymmetric carbon atom.

Effect of Atropin on Hyperglycemia.—The conclusions reached by Ross are based on the following observations: Atropin administered before chloroform anesthesia did not reduce the hyperglycemia. Atropin administered before ether or chloroform anesthesia did not alter the changes in either heart rate or respiration. Chloroform reduced heart rate while ether increased it, a fact which has been observed by others. Chloroform caused more than twice as much respiratory inhibition compared to that of ether. A two days' fast decreased chloroform hyperglycemia and did not affect ether hyperglycemia. Chloroform asphyxiates markedly more through respiratory inhibition and reduced heart rate than ether. This asphyxiation is the probable cause of a large part of chloroform hyperglycemia and the cause for its not being altered by atropin.

Effect of Antipyretics on Hearing.—The effect of a large number of antipyretic and analgesic drugs and of their combinations was studied by Macht and his associates in the relation to the acuity of sound perception. It was found that acetanilid, sodium salicylate, acetylsalicylic acid, phenyl salicylate, and some other drugs decrease the threshold of hearing. Acetphenetidin, antipyrin, pyramidon and some other drugs increase the threshold of hearing. The effects of various combinations were found to produce results which in the case of some, were addictive, while, in case of other combinations, were of a synergistic character; and the significance of these phenomena is discussed in the text.

Iodin Absorption from Skin.—The observations made by Wetzel and Sollmann indicate that the normal human skin is a very poor channel for the absorption of iodine even in the free state.

Surgery of Kidney.—Of the 239 patients on whom nephrectomy was done in the Mayo Clinic, seven (2.9 per cent.) died. Three had tuberculosis of the kidney; one died of tuber-

culosis bronchopneumonia, one of miliary tuberculosis of the lungs and tuberculous peritonitis, and one of chronic nephritis and bilateral pleuritis. Two of the patients had pyonephrosis; one died of hemorrhage (forceps on pedicle) and one of thrombophlebitis of the inferior vena cava, the common, internal and external iliac veins. One patient with hypernephroma died of an infection. This patient was operated on by the transperitoneal route. One patient with carcinoma of the kidney died of acute nephritis and metastatic carcinoma in the lungs.

Tuberculosis of Spine.—Of 405 patients with Pott's disease observed in the Mayo Clinic, 100 were operated on by a modified Albee bone grafting method. Meyerding states that it has been their experience that the most favorable results are obtained by a proper selection of patients to be operated on and the continuance of the conservative treatment after operation until in the judgment of the surgeon, the disease process has been arrested. The bone graft used was curved to fit the deformity. Eighty-six per cent. of the patients in the series have been relieved of clinical symptoms; three patients are unimproved; three have not been heard from; eight have died since operation.

Is Sprue Endemic in South?—Evidence is given by Boyd to substantiate the view that this infection is endemic within the Southern United States among individuals who have never been outside of the country.

Coccidioidal Granuloma.—Forty-four cases of this disease have been reported and Lynch adds one more. Forty-one patients were residents or former residents of California. One case originated in Colorado, one in Missouri; the first in the Argentine, and the forty-fifth in South Carolina. The San Joaquin Valley of California has been the source of the majority of reported cases. The author's patient was a colored woman, aged 45 years. She was born and had lived on one of the sea islands near Charleston, had come to work in Charleston as a household servant and had never been out of this region. The case was a typical one in every respect.

Control of Malaria by Quinin Sterilization.—This paper is a brief historical review of the developments and progress of

malaria control work in Bolivar and Sunflower counties, Mississippi, with which Bass has been associated.

Inguinal Hernia of Uterus.—Royster's patient was a colored woman, 45 years of age. She had been married twice but had never been pregnant. Her menses, occurring first in her fifteenth year, had always been vicarious, the flow proceeding from her nose regularly every twenty-eight days. Each month, following the discharge from her nose, she suffered from headache and pain in the epigastrium or in the thighs. About the age of 14 a lump was first noticed in her left groin, but it gave her no trouble and very little attention was paid to it until two months before admission, when she began to experience pain and discomfort. According to her impression the mass had enlarged rapidly for the previous twelve months. An incision over the mass along the groin revealed a hernial sac containing a uterus somewhat larger than normal which harbored a fibroid of the size of a billiard ball. The pedicle was composed of the well developed left tube and ovary with the broad ligament. The specimen showed complete absence of the right tube, ovary and broad ligament.

- Congenital Redundant External Meatus; Repeated Abscess Formation; Excision. D. McKenzie.—p. 30.

Treatment of Infantile Paralysis.—The outstanding lines of treatment on which Mackay lays emphasis are complete anatomical rest and muscle reeducation. The treatment for any paralyzed muscles is immediate and anatomical rest. It must be immediate; it admits of no delay because the disease at once destroys muscle adjustments, and so fine are these that immediately the nerve cell governing the action of a flexor, for example, is affected, its extensor opponent begins to overact, and this must be prevented. No definite time can be stated as to when muscle reeducation should be begun, but the guides will be pyrexia, pain and tenderness; until the cessation of these the limbs are best kept at rest. The great underlying principle is to pick up a minimum function and to use it as the commencement. There is a zero position of muscle function for every muscle or muscle group; reeducation must be commenced in this position, and carried on patiently and skilfully during the next two years at least.

Leukemia with Scalp Nodules.—A boy, aged 3 years and 4 months, with an apparently idiopathic severe anemia of 11 per cent. hemoglobin and 760,000 red cells, responded, as evidenced by his general condition and blood picture, to treatment in five weeks. Then he contracted measles, and about three months later he developed nodules, mainly in the scalp, exhibiting at the same time a different blood picture, a hemoglobin percentage of 72, red cells, $5\frac{1}{2}$ million, together with myeloblasts. Without treatment some of the nodules disappeared and others became smaller, but with a reduction of the red cells and the hemoglobin content. With the commencement of treatment, post hoc or propter hoc, the temperature shot up and a soft tender tumor developed. The treatment was discontinued for a fortnight, and recommenced owing to the steadily increasing anemia, but with no evidence of any improvement; eventually, with all the accompaniments of any severe anemia, death took place. Of unusual occurrences were tender hyperemic swellings in connection with the lower ends of the bones (tibiae and right femur) which subsided in a few days; the gradual enlargement of the nodules with the decline of the patient's condition, and the disappearance of some of these twenty-four hours before death.

Cardiac Angina in Child.—A boy, 6 years old, with a negative history, was found suffering from a dry pericarditis and anginoid attacks of considerable intensity. Under treatment these attacks ceased.

- *Etiology of Diverticulitis. C. H. Willey.—p. 631.
- *Etiologic Factors in Abortion. D. Dougal and J. W. Bride.—p. 632.

Transfusion of Blood in Eclampsia.—Bell reports a case in which 500 c.c. of blood were transfused into an eclamptic. The husband was the donor. The blood was withdrawn into citrate solution from his median basilic vein. Approximately the whole of this was transfused into the median cephalic vein of the patient. The patient made a good recovery.

Temperament and Diverticulitis.—The three patients seen by Willey were suffering from looseness of the bowels. One of these was found to be suffering from an acute kink resulting from adhesions of the sigmoid to the parietal peritoneum, and the other from a fistulous communication between the sigmoid and bladder. Willey thinks it would be illuminating to note in all cases the particular type and build and temperament of the patients, as well as any temporary condition of mental worry or powerful emotional disturbance. He has no doubt of the very close connection between depressing emotion and pathologic conditions of the large intestine, and suggests that this is the first stage in the creation of diverticulitis, a sensitive and impassioned temperament being the most powerful predisposing factor. In men of this build the effect of acute emotional worry tells at once in some way on the large intestine. The colitis of worry evidently results from diminished trophic innervation and tissue resistance, while at the same time the natural digestive ferments are faulty in quantity and quality. Food and the mucous lining become morbidly septic. The *B. colic* becomes more and more virulently active. Probably many follicles are infected, which may account for diverticuli being multiple.

Etiology of Abortion.—One hundred cases were analyzed by Dougal and Bride as to causation. Accidental or reflex causes were present in 18 per cent. General disease of the mother, disease or displacement of her genital organs, and gross abnormalities of the fetus or placenta (other than those due to hemorrhage or infarction) were found in 25 per cent. Syphilis, as represented by a positive Wassermann reaction, accounted for 12 per cent. but its influence as the actual cause of the abortion was probably much less, and nearer 8 per cent. From the remaining 52 per cent. has to be deducted the figure for the self-induced group, which is probably not less than 20 per cent. In the present series, 8 per cent of the women admitted taking lead pills, and a number of these showed clinical evidence of lead poisoning. This leaves over 30 per cent. of cases with no cause assigned. Pathologic investigation throws little additional light on the subject, as most of the morbid changes found do not produce the abortion, but occur during the operation of some other cause. It would appear, however, that the mother is primarily at fault as the result of some diseased condition, whether it be of an organic nature or an increased irritability of the centers presiding over the expulsive action of the uterus.

- *Functions of Suprarenal Glands in White Rats. H. V. Exner.—p. 79.
- *Approach to Median Nerve in Forearm. A. A. McConnell.—p. 90.

Compression Neuritis.—Wheeler reports one case of this type in which he removed the first rib. An incision was made above the clavicle, as if for ligation of the subclavian artery. A second limb was added, running parallel to the fibers of the trapezius muscle. The segment of rib removed extended from the posterior edge of the insertion of the scalenus medius to the scalene tubercle, so as to include

the groove for the subclavian artery, and the trunk formed by the eighth cervical and first dorsal nerves.

Function of Suprarenals.—The results of his extensive experimental work have convinced Exner that the glycogenic function of the suprarenals is dependent on, or works in conjunction with, some nervous control; this nervous control, when adequately stimulated, still being able to produce glycosuria independently, and in the absence of all suprarenal tissue. Whether the converse is true is a matter for speculation, but whatever the glycogenic function of the suprarenal glands may be, it seems to be subordinate to and dependent on the central nervous system.

Exposure of Median Nerve in Forearm.—The simplest method of reaching the plane between the superficial and deep muscular groups, where this nerve lies, according to McConnell, is to make an incision along the free border of the flexor carpi ulnaris muscle. On retracting this muscle, the interval between the flexor sublimis and flexor profundus muscles is immediately exposed. The ulnar artery and nerve are seen lying on the flexor profundus. A retractor is then inserted deep to the flexor sublimis, and the muscle is drawn anteriorly and laterally, thus exposing the median nerve in the greater part of its course in the forearm. With full flexion of the wrist the nerve lies easily accessible down to the transverse carpal ligament.

Pathogenesis of Deficiency Disease.—Diets which are deficient in vitamins and in protein, and at the same time excessively rich in starch or in fat or in both, McCarrison found to be potent sources of disease and especially of gastro-intestinal disease. An excess of fat, in association with deficiency of B vitamin and protein and superabundance of starch, is peculiarly harmful to the organism. Certain dietetic deficiencies greatly favor the invasion of the blood and tissues by bacteria, especially is this the case when deficiency of vitamins and protein is associated with an excessive intake of starch. Complete absence of this vitamin from the food of the human beings is of less practical importance, from the point of view of disease production, than is its subminimal supply. Complete deprivation of B vitamin, especially in the presence of imperfect balance in other essential requisites of the food, will lead to rapid dissolution and death; subminimal supply of this vitamin will lead, in like circumstances, to slow dissolution and disease.

Cancer of Stomach and Vitamin Deficiency.—McCarrison is inclined to attribute the malignant growth in a monkey to the deficiency of certain food factors. The monkey was fed on food which contained an adequate supply of A and C vitamins but was deficient in B vitamin. The animal survived this dietetic regimen for fifty-one days. At the necropsy an obvious carcinoma of the stomach was found. The discovery of this area of carcinoma was largely a matter of chance since there was no macroscopic evidence of its presence. That the carcinoma was of recent origin seems probable since the area of pyloric mucosa involved by it was of very small size.

Value of Wassermann Test.—Twenty-two per cent. of an apparently healthy Indian male adult population tested by Iyengar, without selection, showed latent or clinically inactive syphilis as demonstrated by the Wassermann test.

Value of Wassermann Test in Leprosy.—Iyengar examined the blood serum in 100 cases of undoubted leprosy, all patients being males. Thirty-four cases were nodular, fifty-two of anesthetic, and fourteen of the mixed form of leprosy, respectively. The number of positive Wassermann reactions were for these several types 17, 16 and 8, respectively, which is 41 per cent. The author is convinced that this reaction is characteristic of leprosy in these cases and that it is not syphilitic.

- *A New Vaccine. J. Hishikari.—p. 289.
- Biological Study of Vibrios; Toxin Against Blood Corpuscles. T. Yoyoshima.—p. 289.

New Vaccine: Bacterial Solution.—Hishikari has prepared a vaccine which is not a bacterial suspension, but a solution, in which antigen may remain unaffected by the dissolution of bacteria. Ten platinum loopfuls of a twenty-four hour old culture are mixed with 10 c.c. of a 2 per cent. dried sodium carbonate solution and the mixture is allowed to stand for twenty-four hours in the incubator at 37 C. The bacteria will then dissolve in the mixture. The mixture is neutralized by adding 1 c.c. of an 8.4 or 8.7 per cent. acetic acid solution. To this neutralized solution is added urea to 0.52 per cent. In the preparation of the vaccine of putrefactive cocci and the streptococcus of elephantiasis, the cocci must be killed by keeping the suspension in the water bath at 50 C. for two hours before it is neutralized, for these will not be killed even when they are kept for twenty-four hours at 37 C.

- Excretion of Urea and Chlorate Salts from Kidney. G. Enami.—p. 314.
- Treatment of Gonorrhea. S. Hidaka.—p. 314.

Volumination: New Immunization Phenomenon.—By mixing bacteria with the normal serum, the bacterial bodies will be seen to swell. By employing immune serum, instead of the normal serum the swelling will appear more remarkable. This volumination, as it is named, occurs even in the presence of so small quantity of salts as would never cause agglutination. From these facts, the swelling of the bacterial bodies may be considered to be the results of the direct combination of the antigens and antibodies.

Schlatter-Osgood Disease.—The author is inclined to attribute the cause of the disease to the incomplete ossification of the independent bone nuclei. The immediate cause of avulsion may, therefore, be disposition and stress.

Pellagra: Rôle of Parotid.—In view of his findings Enright believes that the "food deficiency theory," which has been considered on apparently adequate grounds to be the cause of pellagra, is seriously threatened; that a food deficiency can be quite excluded, but it can hardly be considered as of paramount importance. Obviously something more than a dietetic factor is involved. A critical analysis of the diets which German pellagrins ate before capture and during their period of captivity prior to the onset of the eruption is sufficient to explode the food-deficiency theory as a predisposing factor. That the pellagrins suffered from defective digestive assimilation is undoubted. The incidence of malaria and dysentery was very high, and was responsible for intestinal derangement, which was a marked feature of the majority of the cases. Judging from the indicanuria commonly present and the copious foul smelling evacuations which frequently contained undigested food material, it is evident that there was abnormal protein decomposition, and that the ultimate good effects of the diet were largely vitiated or entirely lost in this manner. Enright wonders whether the parotid possesses any rôle in protein metabolism. He suggests that this gland may possess an internal secretion, the function of which is concerned in the economy of protein, just in the same manner as the pancreatic secretion is essential for normal carbohydrate metabolism.

Traumatic Intussusception.—In Kennedy's case a very early intussusception was discovered four and a half hours after a street accident. Kennedy accepts this as being direct evidence that injury may cause intussusception.

*Tuberculin Treatment of Tuberculosis. D. M. Macrae.—p. 217.

Tuberculin Treatment of Tuberculosis.—Several hundred tuberculosis patients have been treated by Macrae with T. B. E. of Wright and according to Wright's technic. The patient was usually put to bed in the open air until the pyrexia—when present—had subsided. Tuberculin was then given as indicated, the dose being carefully graduated each week, having regard to the nature of the case. The injection was given subcutaneously, and absolute rest for twenty-four hours after was strictly enjoined in each case. Each week the dose was increased by $\frac{1}{10,000}$ mg. or more, according to the patient's progress, until $\frac{1}{2,500}$ mg. was reached. No ill effects were observed from the treatment of serious cases with tuberculin. In fact, Macrae found that in very early cases of pulmonary tuberculosis patients seemed to be benefited by injections of tuberculin. On the other hand, however, other patients did equally well without it; and if it be true that 95 per cent. of the human race have, at some time or other, been tuberculous, it must be equally true that most of them have recovered without any kind of treatment. In

surgical tuberculosis the case was different. In all glandular affections it was found that incision, followed by tuberculin treatment, was of value.

The Heart in Diphtheria.—Aviragnet and Lutembacher call attention to the great affinity of diphtheria toxin for the heart, about the same as for nerve tissue. The intensity of diphtheric paralysis parallels the cardiac manifestations, as they are both the expression of the common intoxication. The toxin attacks the heart muscle proper as well as the more highly differentiated parts of the heart. The arrhythmia depends on the degree of the toxic impregnation, and disappears with it, but often tachycardia persists for weeks and even months.

The So-Called Azurophil Granulations. L.M. Bétancés.—p. 66.

Aneurysm of the Left Ventricle.—Lutembacher states that constant pain at the apex of the heart is the only sign of value that he has been able to discover for the existence of an aneurysm of the left ventricle. It is sometimes violent but more commonly it is a dull ache or merely an uncomfortable sensation in the chest, accentuated by pressure. He gives illustrations of his three cases.

Sinus Arrhythmia from Asphyxia.—Gallavardin reports two cases from which he assumes the possibility of sinus arrhythmia with large waves for which the asphyxia is responsible, by its stimulating effect on the nuclei of the vagus. Apneic and postapneic retardation is the most characteristic form.

Sino-Auricular Block.—Gallavardin and Dumas report a case from which they conclude that abnormally low bradycardia (between 32 and 36 pulse beats) is due to sino-auricular block. Violent exertion would restore in their patient normal rhythm for the time being. As this normal episodic rhythm gave way again to the primary bradycardia, all gradations of arrhythmia characteristic of partial block could be noted. Swallowing movements restored normal rhythm to a certain extent. They could not decide in their case whether the bradycardia from sino-auricular block was the effect of a congenital predisposition or of a lesion in the sino-auricular system.

Acidosis in Acute Abdominal Disease.—Labbé insists that tests for acidosis should be applied to all patients as a routine measure, as much as for albuminuria and glycosuria. He uses the Gerhardt, Legal or Lieben tests for diaceturia and acetoneuria, and has found the results important for both diagnosis and prognosis. He ascribes the acidosis to disturbance in liver functioning secondary to the infection. It has the same import as insufficiency of the liver from other cause, but he warns that the liver may be gravely affected without acidosis developing.

Bismuth and Kaolin in Treatment of the Stomach.—Hayem remarks that nowadays he never meets any one that takes sodium bicarbonate systematically to relieve pain in the stomach except persons from other countries who are unacquainted with the French method of giving a single dose of 20 gm. of bismuth subnitrate in the morning, fasting. He introduced this treatment in 1906, and time has confirmed its efficacy. He has never witnessed any instance of toxic action from this large dose, but he has found kaolin very nearly as effectual as bismuth, as was described in the Paris Letter, May 29, p. 1531.

Hydroparotitis from Artificial Teeth.—Jarret calls attention to a recurring swelling and pain in the parotid gland which is liable to develop when artificial teeth are worn. If the patient has happened to take out the plate when being examined, the physician may be misled.

*Functional Hyperthermia in Children. H. Jumeau.—p. 362.

Functional Hyperthermia in Children.—Jumeau states that during childhood many so-called obscure febrile and subfebrile conditions for which a pathologic cause is sought in vain are in reality purely physiologic hyperthermia and not fever. The adult is a stabilized individual; the child, on the other hand, is an organism seeking to acquire a definite equilibrium. There are many physiologic causes that may produce a variation of temperature in children; of these causes exercise is perhaps the most important. The child is more active than the adult, and activity causes a rise of temperature. A walk of 3 miles at an ordinary gait will raise the temperature of a child, sometimes as high as 100.2 F. Hyperthermia may be of alimentary origin. A nursing, during the menses of its nurse will often have a temperature of 100.4. In early childhood the temperature falls a quarter of an hour after eating, then rises about a degree. The temperature is also influenced by the character of the food. Nervous children are naturally more subject to fluctuations of temperature than others. However, the physician should not make a diagnosis of functional hyperthermia until he has made a careful examination of the child and excluded pathologic hyperthermia of obscure origin, of which latent tuberculosis is one main cause.

Pleuritic Hemiplegia.—The young man with acute left pleurisy and large effusion developed the twelfth day, four days after a simple exploratory puncture, persisting organic hemiplegia. Two similar cases are on record. Puncture earlier might have warded off the embolism presumably responsible for the hemiplegia. The effusion had collected very rapidly and this should have warned to puncture early.

Roentgen Raying of the Spleen in Malaria.—Cordier's two years of experience have confirmed the advantages sometimes to be derived in rebellious malaria from roentgen exposures of the spleen.

*Nerves of Arterial Sheath in Causation of Eczema. R. Leriche.—p. 651.

Neuralgia from Malformation of the Fifth Lumbar Vertebra.—Nové-Josserand reports five cases in which patients complaining of pain in the sacrolumbar region were found on roentgen examination to present malformation of the fifth lumbar vertebra, an abnormal development of the transverse processes which were too long, and often too wide, crowding the fifth lumbar nerve. The fact that when the malformation is unilateral the pain radiates from the same side would seem to furnish strong proof that the malformation is the direct cause of the pain. Resection of the transverse processes does not seem irrational in treatment of this sacralization of the vertebra, causing lumbar neuralgia.

Pathogenesis of Decalcification of the Bones.—According to Tillier and Witas, decalcification of the bones is of various origin. It may be postinfectious and represent the defense reaction of the bone marrow which hypertrophies at the expense of the mineral elements of the bones. Or it may be due to faulty nutrition related in turn to some lesion of the central nervous system. It may be associated with vasoconstriction, dependent on conditions in the sympathetic nervous system. Or it may be traced to a direct local irritation of the sympathetic nerve fibers, which causes a circumscribed decalcification of the bone adjacent to the lesion, usually traumatic. The manifestations may be of a reflex character, associated with phenomena affecting primarily the muscles and of the same origin. Close relation between the decalcification and the pain may be evident. In this case the irritation of the sympathetic system has entailed neuritis.

Cure of Eczema Associated with Varicose Veins.—Leriche gives an account of a case of moist eczema of the leg associated with varicose veins which had resisted all forms of treatment for a period of five years, but which receded completely in a few days following denudation of a stretch of the femoral artery—what he calls perifemoral sympathectomy.

- *Artificial Feeding of Infants in Institutions. A. Mola.—p. 65.
*Common Diarrhea in Infants on Cow's Milk. Marfan.—p. 81.
The Milk Supply in Paris and Suburbs. H. Martel.—p. 107.

Artificial Feeding of Infants in Institutions.—Mola reviews the work of the infant ward at Montevideo, showing that it compares favorably with similar institutions elsewhere. But even at the best, over 38 per cent. of the infants artificially fed died before reaching the sixth month; from 6 to 12 months old the mortality was 15 per cent., and from 1 to 2 years was 3.9 per cent. Institutional care of infants is pernicious at the best from the lack of psychic stimuli and the danger of secondary infection. The mortality of 19 per cent. for infants in the institution for three weeks rose to 50 per cent. with an eight months' stay. During the last six years a total of 1,026 infants have passed through the service; the total mortality has averaged 17 per cent. The rooms are spacious and there is a large court for sunning the babies and one nurse to each four. He remarks in conclusion that there is nothing more individual than the need for food; health and normal growth can be obtained with very different rations according to the subject. Sometimes the infant will begin to thrive for the first time when the amount of food is reduced to much below the normal standard. Over 64 per cent. died of the artificially fed infants weighing less than 3,000 gm., while the mortality was only 17.1 and 2.8 per cent. among those weighing 5,000 and 6,000 gm.

Diarrhea in Infants Fed on Cow's Milk.—Marfan explains that common diarrhea in infants getting cow's milk is due to exaggeration of peristalsis and hypersecretion in the bowel, a reaction to irritating substances which may be of

various origins. The intestinal flora may not have been altered before the diarrhea, but once it is installed, the flora changes and in a way that may maintain or aggravate the irritation from the products of the proteolytic, saccharolytic or lipolytic bacteria. Although these modifications of the flora are the consequences and not the cause of the diarrhea, yet it is important to keep them under control, as nutritional disturbance sets in early from the secondary defective digestion and assimilation.

Syndrome of the Posterior Inferior Cerebellar Artery. Duhot.—p. 259.

Thrombophlebitis of the Upper Extremities.—Cadenat states that this rare condition manifests itself by a syndrome similar to phlegmasia dolens of the lower extremities. It develops in from two to four weeks. As a rule, it terminates by a complete return to normal function, without the occurrence of embolism. Treatment is simple. First immobilization with suspension; then massage and mobilization, beginning with the third week. Phlebitis may result from a local infection of the arm, or it may be due to overstrain or to traumas of the chest that show no infection clinically. He summarizes fourteen cases, including two from his own service.

Appearance and Reaction of the Feces. R. Goiffon.—p. 294.

The Sham Meal Test.—Dupuy discusses the sham meal test recommended by Carnot in 1904 for determination of the quality and quantity of gastric secretion. It is a clinical application of Pawlov's experimental psychical secretion. At the Beaujon hospital the appetizing sham meal usually consists of broiled steak, and bread and butter. The fasting subject is instructed to cut his food fine and to chew slowly each mouthful, but to refrain from swallowing any of the food or saliva. Each mouthful, after thorough mastication is expelled in a basin, the subject rinsing his mouth with water from time to time. The quantity of food set before the patient should require ten minutes for its mastication, as this is the minimal duration of the sham meal, since the psychic secretion reaches its height in about ten minutes. After the meal has been disposed of as described, he keeps quiet for ten minutes longer, during which period he continues to deposit in the basin all the saliva that is secreted. At the end of this time the contents of the stomach are again evacuated with the stomach tube, as was done before the sham meal. From 30 to 90 c.c. of clear gastric juice are thus secured, which contains no food particles if no saliva nor food has been allowed to reach the stomach. The gastric juice thus secured turns diamidoazobenzene red, which is evidence of the high percentage of free hydrochloric acid. Owing to its purity, its analysis is particularly easy. Dupuy has found the method of great value in the differential diagnosis of cancer, ulcer, types of dyspepsia, etc.

Presse Médicale, Paris

April 17, 1920, 28, No. 23

*Early Diagnosis of Hard Chancre. R. Sabouraud.—p. 221.
*Autoplastic Surgical Treatment of Baldness. R. Passot.—p. 222.
*Reparative Surgery of the Hand. C. Lenormant.—p. 223.

Urgency of Early Diagnosis of Hard Chancre.—Sabouraud insists on the extreme importance of ultramicroscopic examination with every dubious ulceration on the genital organs, and reiterates that syphilis should be managed like rabies.

Operative Treatment of Baldness.—Passot utilizes strips from that part of the scalp which is not affected with calvities, twisting the flaps around to cover the bald region, as he shows in two illustrations. The growth of the hair will soon hide the edges of the long narrow pedunculated flaps,

cut to cover about a third of the bald area. The result was a complete and permanent success in his six cases thus treated. By the end of a month the hair had grown enough to conceal all trace of the incisions. By the second or third month the hair had grown long enough to cover the denuded areas entirely. He remarks that this method of *chirurgie esthétique pure* ranks with the operative correction of wrinkles, surgical tattooing of scars, and reconstruction of ugly noses, French surgeons now taking much interest in correction of disfigurements.

Reparative Surgery of the Hand.—Lenormant reviews the extensive literature of the last few years on reconstruction of fingers and of the hand in general. Substitution of the thumb with a toe is giving better results, but the joints can seldom be used actively. When done on a child, the toe does not grow to keep pace with the rest of the hand. The discomfort from the position required to bring the pedunculated toe flap and the hand together also restricts the use of this method. The outcome is more promising when a finger from the other hand is used for the new thumb. Joyce reported in 1918 a successful case, the ring finger of the left hand forming the new right thumb. The hands were fastened together for two months. The man can cut with scissors and otherwise use his right hand normally. Of the nine cases of grafting a finger or toe in place of the thumb, the graft lived in all but two, and the results were excellent.

Intranasal Treatment of Ethmoidal Suppuration. G. Portmann.—p. 233.
*The Abdominocardiac Reflex. Prével.—p. 235.

The Abdominocardiac Reflex.—Prével refers to the acceleration of the heart beat on changing from the reclining to the erect position. He has investigated this in several hundred persons, having a table for the purpose which swings the body without personal effort from the horizontal to the vertical position. There is no acceleration in the perfectly healthy, and he has traced it to the traction from sagging organs, especially the stomach, mechanically irritating the solar plexus. There is no acceleration if the stomach is supported with a band or with the hands. Tachycardia after exertion is probably due in part to the same cause, and both require treatment to restore conditions to normal, more careful mastication and refraining from drinking too much fluids with meals, while the flabby abdominal walls should be given physiologic training, and be supported with a band. By this means a damaged heart will be spared extra work and the sound heart of the athlete spared unnecessary strain.

The New Laws of Inherited Syphilis. Carle.—p. 244.
Immune Bodies in Treatment of Tuberculosis. C. Spengler.—p. 244.
Trachoma. L. Cheinisse.—p. 246.

Critical Glycemia in Diabetes.—Chabanier expatiates on the light thrown on diabetes by the glycemia figure of the plasma when abrupt and intense acetonuria has been induced, by sudden reduction of the carbohydrates in the diet. This will induce acetonuria even in the healthy, but the glycemia does not vary much. In the diabetic it becomes much reduced, and this reduction phase is what he calls the critical glycemia. When there is already acetonuria in the diabetic, carbohydrates should be allowed until the acetone figure is normal; then the glycemia is again the critical figure. He says that this critical glycemia is the most reliable index at our disposal of what is going on in the diabetic's organs. The normal standard is 1 per thousand and any figure above this indicates the abnormal utilization of carbohydrates which is the essence of diabetes. The size of the figure is an index of the severity of the disease and hence of the prognosis. Hyperglycemia in diabetes seems to be a kind of compensating process, like the high uremia with nephritis. The sugar content of the urine is merely a gross sign of diabetes, he affirms; it is not to be compared with the insight afforded by the critical glycemia. The test diet he has found most convenient for the purpose is the clot from 3 liters of milk, all the whey removed, but water allowed freely with it.

Progrès Médical, ParisApril 10, 1920, **35**, No. 15

*Nitrogen Equilibrium of Blood of Cancer Patients. Loeper and others.—p. 159.

The Nitrogen Balance in the Blood of Cancer Patients.—Loeper, Thinj and Tonnet report the results of their investigations on the blood of fifteen cancer patients. They found that cancer, no matter what the localization may be, affects profoundly the nitrogen equilibrium of the organism and more especially that of the blood. This fact is shown by the increase of the residual nitrogen and by the decrease of the relative amount of urea nitrogen. This result is probably due to the secretion by the tumor of proteolytic ferments resembling erepsin, and in some cases possibly by the action of the tumor on the functioning of the liver itself. They regard as especially significant the frequent increase in the amount of urea in the blood in the absence of any renal lesion diagnostically, a finding in sharp contrast with the hypo-azoturia common in cancer patients. In the fifteen cases the ratio between the urea nitrogen and the total nitrogen of the blood was always below normal; in ten cases even lower than 40 per cent., and in four cases below 20 per cent. The residual nitrogen varied around 0.60 gm., although in one case (cancer of the pylorus) the unusually high figure of 1.82 gm. was noted.

Verticotraverse Fracture of Condyle of Femur. Bergeret.—p. 592.

*Infectious Spondylitis and Perispondylitis. Lance and Jaubert.—p. 607.

To Wall Off the Subarachnoid Space in Operating on the Brain.—Lemaitre refers particularly to operations for abscesses in the brain or cerebellum, but the simple method he has applied successfully in sixteen cases can be used for any operations on the brain. The aim is to evacuate the pus and induce adhesions along the tract of the drain to form a fibrous wall, and thus shut off all communication with the meninges. The meninges are not incised, a Pravaz needle being used to puncture down to the focus. When pus appears, the needle is replaced by a catheter. Usually pus will rise in the catheter, and the abscess will thus be partially drained. Then the catheter is removed and a drain of very small caliber is inserted in its place and worked into the puncture hole with care not to tear the edges. The drain is left in place for from twenty-four to forty-eight hours, during which time it does not act so much as a drain as it does as a foreign body designed, through a process of irritation, to develop meningeal adhesions. Then the tract leading to the collection is further enlarged by the insertion of a larger drain. By thus gradually increasing the size of the drains from day to day the meningeal orifice is widened, the area of thickening produced by the adhesions is increased, and the exclusion of the subarachnoid space is complete. Lemaitre thinks that this walling off of the subarachnoid space around marks a distinct advance in the evolution of brain surgery.

Spondylitis and Perispondylitis.—Among 150 patients whose condition had been diagnosed as Pott's disease, Lance and Jaubert found a considerable number with infectious spondylitis, so-called rheumatismal perispondylitis or tuberculous rheumatism of the Poncet type—a total of fourteen such cases from among the military hospital patients and four more from civil practice. At the height of the process the symptoms could not be controlled by any medication and the pain did not cease by mere rest in bed alone, but when the patient was provided with a plaster body cast the pain yielded rapidly. While strict immobilization is indispensable during the pain crises, it seems that later it is better for patients to be mobilized. At the beginning of the exercises the movements were stiff, but after a few seconds patients regain their suppleness. Mobilization must be carried out very gently and very prudently, as any overfatigue may bring on a new attack of pain. Eleven of the patients were treated with heliotherapy for variable periods and all were

more or less benefited. The writers do not pretend that moderate mobilization together with heliotherapy can render supple spines that are already ankylosed, but state that there is no doubt that heliotherapy attenuates and arrests the pathologic process and aids in the resorption of the exudates. Otherwise the cases seemed to be passing on inevitably to ankylosis of the spine.

*Nature of Aphasia. F. Lotmar.—p. 3. Conc'n.

*Organic Variability and Correlations. H. Bersot.—p. 37. Conc'n.

*The Problem of Instinct. R. Brun.—p. 80.

Myokymia and Muscle Changes in Scleroderma. S. Neumark.—p. 125.

Heterotopia of the Choroid Plexus. S. Kitabayashi.—p. 154.

Aphasia.—In concluding this long study of difficulty experienced in finding the proper word, Lotmar emphasizes that the difficulty is much greater for names of unseen objects than for the visible, and that this must be borne in mind, in addition to other points he describes, in training during convalescence from total aphasia.

The Plantar Reflex.—Bersot reviews the literature extensively and explains that reflex action in pathologic conditions is like that of the extremes of life, in infants and the aged. It is the relative frequency and variations that imprint the characteristic stamp, considered in connection with other reflexes.

Instinct in the Light of Modern Biology.—Brun defines the modern biologic conception of instinct and describes its physiology, psychology, and pathology, or "hormopathies." The latter, he says, may be primary morphogenic or metabolic endogenous hormopathies or secondary metabolic or dynamic exogenous hormopathies—all outside of the consciousness and all originating in the instincts for food and for defense.

Epidemic of Cholera in Corfu, 1916. A. E. Tsakalotos.—p. 230.

Are the Erythrocytes Biconcave?—Wyss presents evidence that the erythrocytes in the blood are round or egg shaped, the plasma exerting a counter pressure to the oxygen inside the corpuscles, which maintains them in this shape. The moment the blood issues from the vessel, this counter pressure is lost; the oxygen escapes from the erythrocytes instantaneously, and they collapse into the biconcave shape. The round or egg shape offers much less chance for friction in the circulating blood than if they were biconcave. He suggests that study of the interval before the corpuscles thus shrink to the biconcave form might have diagnostic value in some conditions.

Experimental Research on Action of Drugs on the Intestines by Oral and by Parenteral Administration. F. Uhlmann and K. Zwick.—p. 287. Conc'n in No. 17.

Incapacity from Injury of the Eyes.—Sidler-Huguenin remarks that in estimating the degree of incapacity after injury of the eyes the mistake is generally made of regarding it as greater than it later proves to be. In reviewing the ultimate outcome in 300 cases in which compensation was granted he was impressed with the way in which the subject adapts himself to his impaired vision and seems to regain his old skill to a remarkable degree, as for example, a certain farmer who had lost one eye and can distinguish only fingers at 2 meters is able to manage his farm as before without any apparent detriment. When men gave up their place in the workshop on account of the injury to their eyes, it often happened that they took another similar place elsewhere, or else they founded a similar business of their own with the indemnity they had received. In none of the 300 cases has the other eye been injured later when the men continued at the same occupation. Of the total 300, fully 85 or 90 per cent. resumed their former trade or other work, testifying

that the injury to the eyes does not require a change of occupation unless it is very grave. He was allowed to examine the pay-rolls, and he found that the wages paid (1916) were the same in 81.6 per cent., and only in 8.3 per cent. were they lower. Of those who had resumed work with reduced wages, over half had regained their former wage in a year or two. Fully 90 per cent. of all by the end of two years were getting no less wages than before their accident.

Investigation of the way in which the compensation money had been spent, showed that it had laid the foundation for a competency in a number of cases, fully 80 per cent. of the injured having invested the money wisely, so that their accident had really been fortunate for them, financially. His investigations showed further that the disfigurement from the accident did not interfere with the men's getting work, and the family and friends seemed soon to get accustomed to it. Another important factor in the ultimate outcome is that a single eye gets trained in time to what amounts to stereoscopic vision as it is assisted by the sense of touch. Women become more expert in this way than men, as a rule. The experience with these 300 cases testifies abundantly that after the loss of one organ its mate learns in time to assume the functions of both. He warns that the view that every impairment of vision entitles to compensation as a matter of course is erroneous. Physicians should impress this on the injured, demonstrating to them how certain persons with defective vision even from childhood are yet able to do fine work. Otherwise the physician is liable to lay the foundation for a traumatic neurosis. He should inform the injured that any defect less than 0.75 for fine work and 0.5 for ordinary work does not entitle to indemnity. With graver injury than this, the decision must be left to specialists, but it is well to bear in mind that of the 300 cases on which this communication is based, only 10 per cent. have had their earning capacity reduced by their accident. Instead of speaking of "impairment of earning capacity" it might be better to say that the "integrity of the body is no longer quite intact." This would avoid the suggestion of damage when really such does not exist. It is probable that the experiences with accidents in other fields will yield the same ultimate results as with injury of the eyes.

*Physiologic Acetonuria. E. Pittarelli.—p. 303.

Protein Therapy.—Corinaldesi gave intravenous injections of 1 c.c. of a 2 or 4 per cent. solution of deuto-albumose in a case of typhoid and one of paratyphoid, according to Lüdkke's technic. No benefit was apparent. Then he tried intramuscular injections of 5 or 10 c.c. of sterilized milk in five patients with lobar or bronchopneumonia or typhoid and was astonished at the prompt and permanent improvement that followed one, two or three injections, without disturbances or much local reaction. There was only rarely a slight chill and it was mild. His findings thus confirm the way in which parenteral introduction of some protein substance is able to stimulate the defensive forces and aid in the throwing off of the disease, irrespective of the nature of

the protein inoculated. He remarks that the facts observed have opened new fields of research even if none of the theories advanced to date explain them satisfactorily.

Physiologic Acetonuria.—Pittarelli's research seems to disprove the assumption that every urine contains some acetone. He has further demonstrated that there must be some substance in the urine which combines with the acetone and prevents its responding to the most sensitive tests until the urine has been distilled. Then the acetone is found prominent in the distillate. The nature of this substance that masks the acetone is still a mystery.

The Unstable Temperature in Tuberculosis. Dargallo.—p. 679.

Gangrene After Injection of Sugar Solution.—The primipara of 23 with puerperal fever showed slight and sluggish response to injection of turpentine to induce a fixation abscess. The seventh day she was given an injection of 350 gm. of sugar solution containing 20 drops of epinephrin solution. The injection was made 12 cm. from the point where the turpentine had been injected five days before. This was repeated on the other thigh. Within twenty-four hours a patch of gangrene developed at the site of the injections of the sugar solution, and the processes rapidly spread and burrowed deep. When the gangrenous tissue had been cut away, the aponeurosis was left exposed but under hot applications several times a day the defect gradually healed over. Injection of sodium chlorid solution without the epinephrin was borne without by-effects, so that Baudilio inclines to ascribe the gangrene to the local vasoconstricting action of the epinephrin in the much debilitated and infected patient.

Radium Treatment of Cancer of Uterine Cervix.—Summarized April 10, 1920, p. 1054, when it appeared elsewhere.

Radium Treatment of Uterine Cancer.—Vital Aza describes the modifications in rabbit ovaries under exposure to radium and roentgen rays, and discusses the mechanism of the cure of human uterine cancer. He thinks that the proliferation of connective tissue under the influence of the raying is the result, not the cause, of the destruction of the cancer cells.

The radium and roentgen rays do not have any specific action; they merely exaggerate and hasten the degenerative processes going on, while checking mitosis.

 *Acromegaly and Diabetes Insipidus. G. Pittaluga.—p. 90.

Differential Diagnosis of Meningitis by the Eye Findings.—Ribon recalls that malaria frequently induces subjective and objective changes in the eyes, some visible with the naked eye and others requiring the ophthalmoscope for their detection. Malaria may induce symptoms closely resembling those of meningitis but the meninges are sound. Hemorrhages in the retina are explained by accumulation of the hematozoa in the finer vessels. The ophthalmoscope may reveal likewise malarial neuroretinitis. The discovery of the hematozoa in the blood will permit effectual treatment of the supposed meningitis.

History of Medicine.—This instalment of Albiñana's rambling notes of his trip to France to compile data for a history of medicine is accompanied by illustrations of objects of historical interest from the Bordeaux museum. One skull shows a large trephining opening similar to those found in prehistoric skulls. But this skull is a modern one; the trephining opening was made with the prehistoric flint instruments excavated recently. It took nearly two hours to make the opening with these crude tools.

Acromegaly and Diabetes Insipidus.—Pittaluga remarks that acromegaly is probably accompanied by polyuria more often than is generally recognized, as the polyuria may be transient. The condition may right itself later as compression of part of the pituitary subsides or the parts adapt themselves functionally or anatomically to the compression.

Gallstones and Abscess in Liver Without Jaundice.—Stocker describes a case in which the symptoms from cholelithiasis were long mistaken for stomach disturbances from hyperchlorhydria. There was no jaundice, but the liver was enlarged and painful, the pain spreading to both shoulders, and the gallbladder region was tender. Over thirty gallstones were removed from the gallbladder, and recovery was soon complete after the partial cholecystectomy and incision of the liver which released fetid pus. He emphasizes the necessity for examination of the liver for a suppurating process in cases of gallbladder disease, and warns that the cystic duct may be compressed by glands in the gastro-hepatic omentum; swelling of the duct from the compression may obstruct the lumen and thus entail the clinical picture of gallstone obstruction in the absence of gallstones.

 *Arteriosclerosis and the Blood Pressure. K. Harpuder.—p. 74.
 *Nonpuerperal Osteomalacia. H. Curschmann.—p. 93.
 *Wandering Heart. Rumpf.—p. 118.

Relation Between Residual and Total Nitrogen.—Becher found the proportions between the residual nitrogen and the total nitrogen about the same in all the tissues, except that it was a trifle lower in the blood serum and in the lungs. After nephrectomy, and in persons who had succumbed to renal insufficiency, the residual nitrogen formed a larger proportion of the total nitrogen than in normal conditions.

Retention of Indican in the Tissues.—In contrast to nitrogen, Becher found no indican in the tissues when the kidneys were functioning well. But with incapacity of the kidneys, retention of indican was evident; the larger proportion was found in the blood, only very small amounts in the tissues.

Bilirubin in the Blood.—Bauer and Spiegel regard familial cholemia as a chemical sign that the liver is constitutionally below par. The bilirubin content of the blood seems to keep at a constant figure in different persons in normal conditions but, they say, it can be reduced by drugs that act on the sympathetic system, and increased by drugs that affect the vagus. Exceptionally high bilirubin content of the blood was found with obstruction of the bile passages, weakness of the myocardium, congested liver, and traumatic hemothorax. On the other hand, the bilirubin content of the blood was abnormally low with diffuse kidney disease, tuberculosis, inanition, and cachexia from cancer.

Electrocardiography in the Clinic.—Klewitz analyzes several hundred electrocardiographic curves from eighty-eight persons, including twelve with sound hearts. He found a negative T peak only in cases of organic heart disease, especially disease of the myocardium. The same can be said when the T peak is lacking, but the prognosis is not so grave as with the negative T peak. A positive T peak does not absolutely exclude organic heart disease, but the prognosis is more favorable when the electrocardiogram shows a positive or even weakly positive T peak. He found further that pressure on the vagus affected the rate of cardiac contraction both in the healthy and in those with heart disease; but a dromotropic effect was evident only with organically diseased hearts. He gives the necropsy findings in some cases in which during life the T peak had been lacking, or had been present at first and had disappeared as the condition grew worse.

Blood Gases.—Straub and Meier describe how the reaction of the blood can be determined by the curve of the binding of carbon dioxide with a known carbon dioxide pressure. They give the normal standard as deduced from fifty-six curves from forty-six persons with 320 separate determinations of the carbon dioxide capacity. The findings in one case of polycythemia suggest a buffer action by the erythrocytes.

Arteriosclerosis, Contracted Kidney and Blood Pressure.—Harpuder paid special attention to the condition of the kidneys and the blood pressure in 1,165 cases of arteriosclerosis, mostly men. The arteriosclerosis alone does not entail high blood pressure, not even when it involves the small arteries of the heart and brain, but the blood pressure runs up as the kidneys develop sclerosis of their smaller vessels. The high blood pressure seems to develop independently of the severity of any disturbance in kidney functioning or the extent of the anatomic lesion. We are justified

in assuming damaged kidneys whenever the blood pressure is over 160 mm. mercury.

Nonpuerperal Osteomalacia.—Curschmann asserts that osteomalacia may occur not only from excessive functioning of the ovaries during the puerperium, but also from excessive functioning of the thyroid gland at other periods of life. This assumption was confirmed by the success of treatment with phosphorus and cod liver oil in a number of cases described. Other cases showed that still others of the ductless glands might be involved, and that the derangement might occur with either deficient or excessive functioning of one or more. Excessive irritability of the vagus or sympathetic system may further complicate the clinical picture, as he shows by some concrete examples. In one, after a phase of hyperthyroidism, there was hypofunctioning of the thyroid, ovaries and parathyroids, manifested in the nullipara of 27 as abortive exophthalmic goiter, then myxedema, and after a few years osteomalacia and tetany. He cites in conclusion a case of neurofibromatosis which seems to be traceable likewise to weakness of the ductless glands, as there is associated nonpuerperal osteomalacia. The woman improved under phosphorus.

Movable Heart.—Rumpf describes the roentgen findings with an abnormally movable heart, and emphasizes the importance of breathing exercises to restore tone to the diaphragm, the wearing of a supporting band, and restriction of the evening meal to fluid or soft food, without meat, and with little bread, to ward off distention of the stomach.

- *Protein Therapy for Children. A. Czerny and H. Eliasberg.—p. 1.
- *Hyperthermia with Sclerosis of Basal Ganglions. H. Mammele.—p. 5.
- Capillaries of the Skin in Infants. A. Mertz.—p. 13.
- *Cerebral Rachitis. P. Karger.—p. 21.

Protein Therapy Applied to Cachectic Tuberculous Children.—Czerny and Eliasberg expatiate on the transformation in the condition of certain children with advanced tuberculosis under protein therapy. They used horse serum, and obtained the best results with daily subcutaneous injection of from 0.5 to 2 c.c. Two of the twenty-six cases are reported in detail. A girl of 10, with cyanotic hands and feet, swollen legs, evidently in the demineralization stage with cachexia, almost imperceptible response to the skin tuberculin test, a large tuberculous gland in the neck and a tuberculous focus in the jaw, in three weeks began to improve under two injections weekly of 10 c.c. each of horse serum, to a total of forty-seven injections. By the end of ten months no one would have recognized the plump, rosy child. Nine of the twenty-six children died, but these were apparently doomed when the treatment was begun. The ages ranged from 3 months to 10 years. Of the nine that died all but four were under 2½ years old.

Habitual Hyperthermia with Sclerosis of the Basal Ganglions.—No cause for the constantly high temperature in the 17 months' infant could be discovered until necropsy revealed sclerotic processes in the basal ganglions. Drug tests of the sympathetic nervous system had shown that the temperature anomaly must be of central origin.

Cerebral Rachitis.—Karger states that children with rachitis are mentally backward, they sweat readily from nervous influences and show other anomalies, and the brain is usually abnormally large, although no histologic or chemical changes in it have been detected to date. If a wooden block is laid on the head of a normal infant propped up in bed, it will throw off the foreign weight with its hands or by moving its head, but the rachitic child will let it lie and at most will scream. The softness of the bones does not hinder the child from removing the block; it merely does not think of using its arms for the purpose. It does not begin to walk because it has no spontaneous interest in changing its position. Rachitic children seem to have little sense of taste; they will take cod liver oil or quinin without resistance. Laryngospasm and convulsions, he says, are the only cerebral symptoms of rachitis that have been accorded attention so far. The bending of the legs is not due exclusively to weight

bearing, he explains. Even without weight bearing, the legs are drawn up in the Turkish fashion, and the strain from the muscles in time curves the soft bones. There is every reason to get rachitic children on their feet as early as possible on account of the effect on the general health and especially on the intelligence; and on their interest in their environment and to ward off hypostatic pneumonia. He noted extraordinary improvement in one case in which a rachitic child, isolated on account of an acute infection, was placed with another child isolated for the same purpose. Guarding its toys from encroachment, etc., roused dormant energies. In short, he concludes, the cerebral elements are of more moment for the development of the rachitic child than the somatic. Rachitis is not a disease of the skeleton but is a general disease. Not the rachitic bones, but the cerebrally abnormal rachitic child is what we have to treat.

Münchener medizinische Wochenschrift, Munich

- Composition of the Blood in Arid Climates. J. Grober.—p. 1495.
- The Military Hospitals of the Foe. E. Michels.—p. 1495.

The Etiology of Mongolian Idiocy.—Stoeltzner found that in three of ten cases of mongolism the mothers during pregnancy had presented constipation, little appetite for food, striking tendency to take on fat in spite of moderate quantity of food eaten, falling out of hair, hypohidrosis, chilliness, great languor, increased need of rest and sleep apathy and decrease of mental activity—a clear picture of hypothyroidism. Whether there is a causal connection between this syndrome and mongolism Stoeltzner is not prepared to state, but the definite proof of such a causal relation would open the way for active prophylaxis. His findings sustain Lanz' conclusions from his experimental research on the offspring of thyroidectomized animals (1905).

Eruption and Diarrhea During Luminal Treatment.—Haug prescribed in two severe cases of epilepsy 0.1 gm. of luminal three times a day, as recommended by J. Müller. Four weeks in one case, and eleven days in the other after this treatment had been begun, the patients developed high fever, diarrhea with mucous stools, bloody in the first case, and in both an eruption resembling that of scarlet fever, covering the whole body except the face and hands. The total amount taken had been 8.4 and 3.3 gm., and the first patient seemed to be severely ill, with slight stupor. The other presented albuminuria. After suspension of the drug the symptoms subsided in a few days.

- Prognostic Value and Treatment of Important Cardiac Arrhythmias. K. Grassmann.—p. 46. Concl'n.

Pathologic Excursions of the Diaphragm with Paraneuritis and Tuberculous Peritonitis.—Foerster has found pathologic movements of the diaphragm, as revealed by roentgenologic examination, of value in the differential diagnosis of paraneuritis and tuberculous peritonitis, especially in children. Bilaterally with the latter, and unilaterally with paraneuritis, he has observed an upward displacement of the diaphragm with a flattening of the cupolas, obliteration of the phrenicocostal sinuses and marked interference with the respiratory movements. He has never noted this condition with appendicitis, cholecystitis or pyelitis.

Fractures and Plaster Splints.—Von Brunn states that while serving as expert he was astonished to note the large number of bone fractures that heal in an unsatisfactory manner. Either the setting of the fracture had been done improperly or the neighboring joints had been allowed to become stiff. In many cases it was evident that the fracture

had not even been diagnosed as such, which in this era of roentgen rays he finds inexcusable. One common source of error was that fractures of the radius were wrongly diagnosed as sprains. Even when the fracture had been correctly diagnosed, the surgeon had not persisted long enough but had stopped short of normal apposition. When the reduction of the fracture may have been satisfactory, frequently sufficient care had not been taken to make the result permanent, and the bone fragments had not healed in the position assumed when the fracture was reduced. He emphasizes that the common commercial ready-made splints do not usually fit the fracture as they should, and that the surgeon would do well to make his own. He describes in detail his method of preparing plaster splints and points out the advantages of the method.

Significance of the Secretions of the Prostate and the Seminal Vesicles.—Böttcher states that in addition to the three commonly recognized functions of the secretions of the prostate and the seminal vesicles they furnish a protective colloid that counteracts the acidity of the vaginal secretion until the spermatozoa have had time to reach the interior of the uterus.

Examination of Tuberculous Sputums by the Zinc Precipitation Method.—Von Fejér and von Schulz had found the Ditthorn and Schultz enrichment process for tuberculous sputum superior to the Uhlenhuth process, especially when examining a large number of specimens, because of the time consumed in centrifuging with the Uhlenhuth method. But they discovered that in the Ditthorn and Schultz method the specimens, when not properly fixed by heat or if left too long in the carbofuchsin solution, take on a dark color which makes the search for tubercle bacilli impossible. They describe a modification which avoids this, and in 1,129 specimens of sputum 16.9 per cent. were positive by their modified method and only 13.8 per cent. by the Ditthorn-Schultz method. The specimen of sputum is rendered homogeneous and fluid by the usual means, and then equal quantities are poured in two sedimenting tubes. To one tube 0.5 cm. of a 20 per cent. solution of ferrous chlorid is added; to the other, 0.5 cm. of a 20 per cent. solution of either zinc acetate or zinc chlorid (the two salts are equally good). With this quantity of the reagent the resulting precipitate can be easily examined on a single slide. The tubes are allowed to stand for several hours, and when the sediment has been precipitated most of the supernatant fluid is poured off. The sediment suspended in a small quantity of the fluid is transferred to a square of filter paper several layers thick. In a few minutes, when the superfluous fluid has been absorbed, the sediment, still damp, is spread on the slide in a moderately thick layer. When it is dry, fixation over a flame follows and staining completes the process.

Clinical Training of Medical Students at Copenhagen.—Røvsing describes the system of what he calls "volunteer service" by the medical students in the hospitals, saying that it is peculiar to the University of Copenhagen and has been in vogue there for centuries. The students now have asked to have the period for this service reduced from twelve to six months, and he argues against this, saying that the

university may well be proud of this feature. He had special occasion to note its workings during the World War as the newly fledged Danish physicians serving in the various hospitals of the belligerents compared most favorably with the average from other nations.

Gas Phlegmons After Injection of Stimulants.—Thomsen relates that he knows of ten cases in which a gas phlegmon developed at the site of injection of a stimulant during the recent epidemic. In testing means for sterilizing, he found that solutions of morphin, cocain and certain other drugs passed through the Berkefeld filter without loss. After evaporating the filtrate the residue weighed the same.

*The Fat in Diabetes. H. C. Geelmuyden.—p. 479.

Standard Weight and Height Between Two and Six.—Schiøtz tabulates the findings in 513 children of this age in Norway, and compares them with similar statistics up to the age of 17, pointing out certain laws and seasons which seem to control the physical development.

After-Reduction of Congenital Dislocation of the Hip Joint.—Among the points emphasized by Bülow-Hansen in the after-care is that adduction should never be done until after pronation of about 90 degrees. Also that even when the roentgen rays show the head concentric in the acetabulum, if there is any contracture of the adductor muscles, he stretches the adductors under general anesthesia and applies a cast anew for two or three weeks, resuming then massage and exercise. In one girl of 6 the bilateral luxation was ideally corrected on one side but on the other the neck of the femur fractured and the leg was 6 cm. shorter than its mate. He advised against further intervention until the child had grown up. At 18, slanting osteotomy on the leg of normal length shortened it for nearly 6 cm. so the legs are now even.

Influence of Physical Exertion on the Heart.—Dedichen's study of 226 ski runners before and after a 50 km. race over a difficult course, and of 361 athletes traced over six years, demonstrates that neither at the time nor later was there any injurious influence on the heart when the ski athletes were at least 20 years old, healthy and in good training. The control over adequate training is possibly not quite severe enough. Hypertrophy of the heart was found later in 13.8 per cent. but nearly all the ski athletes were laborers, doing heavy work. The hospital records of 459 laborers doing heavy work showed hypertrophy of the heart in 8 per cent. and necropsy records showed up to 33 per cent. In one of the ski athletes the heart was hypertrophied, 15.1 cm. in diameter, but he refrained from the sport and from heavy work for a year, and by that time the diameter was only 13.5 cm. for weight of 68 kg., height 170 cm., and in every respect the health has kept perfect to date.

Fat Metabolism in Diabetes.—Geelmuyden's comparative study of the acute diabetes in pancreatectomized dogs and human diabetes has, he thinks, thrown light on the processes in the intermediate metabolism and their genetic connection, especially in regard to the production of sugar from fat. In research of this kind, he emphasizes, all the changes in the metabolism must be taken into account, not only the glycogen and blood sugar, the glycosuria and the ketonuria but the migration of fat, the transformation of albumin, the total metabolism and the transformation of energy. Such studies hitherto have been restricted to only some of these elements and their interrelations have been overlooked. He shows that carbohydrates promote the formation of sugar from fat, and that the output of sugar is not increased by feeding fat unless a certain amount of carbohydrate is given with the fat. This he thinks is probably the reason why carbohydrates are so injurious in human diabetes. Diabetes in pancreatectomized dogs seems to be due to the very same anomaly in the metabolism as in human diabetes. The chief difference between them is that it occurs suddenly in the dogs while in man it is of long, slow development.

CONSERVATION OF THE MENSTRUAL FUNCTION*

W. J. MAYO, M.D.

ROCHESTER, MINN.

The surgeon approaches his work with the physical condition of the patient in view. He achieves a tangible success, but occasionally is not rewarded by the gratitude of the patient because of intangible changes in the nervous system which follow the operation. Physical cure is sometimes purchased at the price of nervous instability; and we speak wisely of neurasthenia, psychosis, neurosis and hysteria. Often the same physical cure could have been obtained without creating the disturbances so troublesome to the patient, the family and friends. Christian (?) science (?) and similar cults go to the other extreme, refusing to recognize the physical and considering only the psychic.

The central nervous system has a short heredity; its characteristics are not fixed, but unstable, especially in some families. The central nervous system is influencing, to a great extent, visceral functions that existed long before its development. Attempts at retroactive controls always have many exceptions in law, and are physiologically troublesome in man. The nervous system in man weighs as much as the liver and has as many or even more possibilities of functional disturbances, because it is less stable in its functions. The only difference is that the bile function can be seen, and disturbed thoughts cannot be seen—only their results. One group of physicians will say that all these psychic disturbances have a physical basis, apparently believing that a physical basis exists only outside the central nervous system. They then begin very properly to hunt for the cause of these disturbances, and often very improperly attempt to place the blame for them on some real or fancied physical defect with which there is little or no connection.

The uterus, the ovaries and the tubes have chiefly suffered from these misguided efforts at relief, efforts apparently based on the conception that woman's psychic disturbances are generated in her reproductive organs. After all, it is the mental and not the physical which controls our estimate of man.

To one who has had occasion to observe the results of surgical operations on the reproductive organs of women, the truth of these remarks is self evident. Today I consider every surgical disease of the generative organs of women with their future ner-

vous condition in mind, as well as the physical state which is desired. In many instances there is no choice. In malignant disease of the generative organs radical operation is necessary to save life, with relatively small regard for the future mental condition of the patient. In cases of benign neoplasms and inflammatory disease, however, the future condition of the patient as related to the operation, *psychic* as well as physical, must ever be remembered. Happiness is a state of mind, and a state of mind is not necessarily a state of body. This belief is borne to the consulting surgeon by the large number of women he observes who have been operated on once, twice or many times. Their relations to life are changed, they are put out of touch with their social conditions, and they attempt, ever and again, to gain relief from mental and nervous suffering by further resort to treatment of the physical.

When I began practice, abdominal surgery was in its infancy. The ovaries and tubes were removed on indications that would not be considered today. With the growth of knowledge this practice ceased, but in its place developed many mis-called conservative operations. Instead of being removed, the ovary was subjected to unnecessary tinkering, and the ovary does not stand such operations well. Frequently the patient developed sequelae that necessitated removal of the ovaries later. The small cystic ovary especially has been the victim, not of the surgeon, but of the operator. Following this type of operations it will be found that a group of patients return complaining of what they have been told are adhesions, but without mechanical signs. I have seen a number of patients who have been operated on and reoperated on, with only temporary success, for adhesions that did not produce mechanical symptoms. I have little faith in the common belief that adhesions located by the patient, but which cannot be located by the surgeon, are the cause of serious trouble.

IMPORTANCE OF THE OVARY

The generative organs of women are for the purpose of reproduction. The ovary controls the physiologic cycle, the uterus receives and carries the impregnated ovum to term. The uterus is often blamed for troubles with which it really has little to do. The curet is a much abused instrument. The endometrium is relatively seldom diseased, and a high percentage of menstrual disturbances are ovarian and tubal in origin. A sufficient distinction is not made between irregular bleedings from the uterus and true menstruation. Menstrual blood does not clot. If the blood forms true clots, the endometrium may be suspected, otherwise, the ovary. The ovary is an organ of internal secretion independent of the production of ova. The

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

gonadial secretion of the interstitial cells of the ovary controls the development of the female characteristics. It influences the closure of the epiphyses of the long bones, and is related to the endocrine disturbances to which are due the tall, spindling types of giantism. The effect of the ovary on the individual, including menstruation, is independent of direct nervous connection. Tuffier,¹ in radical operations for pus tubes, removed both ovaries and tubes, sterilized the ovary for surface infection in an alcohol flame or by dipping in tincture of iodine, and planted it between the peritoneum and the abdominal fascia. The menstruation ceased for four or five months, and symptoms of the menopause developed; then menstruation started and continued normally. My colleague, Dr. Sistrunk, has treated a number of cases in this manner.

The effect of the internal gonadial secretion on the breast is marked. Beatson,² in some inoperable cases of carcinoma of the breast, removed the ovaries, and most remarkable changes in the breast took place, with disappearance or partial disappearance of the cancer. The autonomic (sympathetic and parasympathetic) nervous system, acting with the hormones (internal secretions) of Starling,³ controls the functions of the reproductive organs. The sympathetic fibers can be directly traced, and in some of the lower animals (Tasmanian devil) branches of the vagus parasympathetic nerve pass to the horns of the uterus, showing direct cranial connection. The nodes of Keith,⁴ acting through the nonstriated uterine muscle, introduce physiologic connections between the visceral and genital functions.

The internal secretion of the ovary generally is closely related to the endocrine system, and widespread effects are manifest on the cessation of the ovarian function. In several instances I have noted that the ovaries maintain their normal size and apparently function after the removal of the uterus. Twenty-two years after performing a vaginal hysterectomy on a young woman for sarcoma of the uterus, I had occasion to open the abdomen. I found the ovaries apparently normal. The lesson to be drawn is that the removal of the ovary is seldom indicated for inflammatory diseases, and a sufficient amount should be saved, if possible, to continue the menstrual function. The transplantation of ovaries from one woman to another, so far as I know, has not been followed by return of menstruation or impregnation. A few suggestive instances have been reported, however, by Franklin Martin⁵ and by Robert Morris.⁶ Morris suggests that ovarian tissues may have been left in the ovarian ligament at the time the ovaries were removed, and this nonfunctioning ovarian tissue may have been stimulated to action by the introduction of ovaries from another woman. He relates some experiences to confirm this opinion.

The thoughtful surgeon conserves menstruation when the thoughtless operator sacrifices it. On one occasion, a good many years ago, when I was oper-

ating for extra-uterine pregnancy on a young woman greatly exsanguinated, I rapidly removed the ovary with the tube in order more quickly to secure a pedicle. Two years later this patient returned with benign cystadenoma in the remaining ovary. At the age of 24 she was deprived of the right to motherhood; and her menstrual function was lost. In tubal pregnancy it is seldom necessary to remove the ovary. I have operated for double dermoid cyst of the ovaries in many cases in which the larger cyst had destroyed the entire ovary, but I have been able to enucleate the smaller cyst from the other ovary, and to save sufficient ovarian tissue so that menstruation may continue. Without discussing further conservation in benign diseases of the ovaries and tubes, I may add that I have seen acute cases of gonorrheal infection of the tubes, including the ovaries and pelvic peritoneum, spontaneously subside, and several years later the patient has become a mother. It is often best not to molest the chronic inflammatory remnants left after such infections have subsided.

Independent of its rôle in reproduction, the menstrual cycle has a striking effect on the female during the period between puberty and the menopause. All surgeons have seen the shrinkage of the uterus, shortening of the vagina, and trophic changes following ovariectomy. The nervous and psychic changes of the normal menopause are aggravated in young women by operations that check the menstrual flow. *It is probable that menstruation itself has some important endocrine function.* The effect on the patient is essentially the same whether menstruation is stopped by removing the ovaries and leaving the uterus, or removing the uterus and leaving the ovaries. Conservation of the reproductive function is of first importance, but conservation of the ovary for the continuance of its internal secretion and its effect on the production of menstruation is second only to the reproductive function; and even if reproduction is impossible, conservation of the ovary or some portion of it for the sole purpose of continuing menstruation is of greatest importance. The estimation of the probable success of an operation from the patient's standpoint may turn on whether or not the menstrual function is to be lost.

Sacrifice of the reproductive and menstrual functions, however, is not confined to removal of the ovaries, but is concerned in operations on the uterus, especially for myoma. Hysterectomy has become an operation so thoroughly organized that almost every operator has some special bit of technic in connection with it of which he is proud, and many a uterus is unnecessarily sacrificed when a myomectomy would be the better operation and would save both the menstrual function and the possibility of motherhood. Hysterectomy is seldom necessary for benign myoma in a woman under 35, and demands an excellent reason in a woman under 30. At 45, hysterectomy is probably the best procedure. Sutton has shown that 10 per cent. of women who require hysterectomy for fibroids after 50 have coincident malignant disease.

RESULTS OF MYOMECTOMY

It has been argued against myomectomy that it is the more dangerous operation; but in our series of 741 cases the mortality was a shade under 1 per cent. (0.9). Abdominal myomectomy was performed in 617 of the 741 cases, with three deaths, or 0.5 per cent. There were four deaths in the 124 vaginal myomectomies, about 2.7 per cent. Every patient dying in the

hospital, irrespective of the cause of death or the length of time following operation, is counted as dying from operation. Following myomectomy in these 741 cases, thirty-three women raised one child, eleven raised two or more children, and fifteen were pregnant at the time the investigation was made. Twenty-three married women who were sterile before operation had one or more children after operation.

Nineteen pregnant women were subjected to myomectomy because of acute degenerative changes in myomatous tumors, and all lived. Thirteen of the pregnancies were intra-uterine. Eleven of the patients went to term and bore living children; two miscarried within a week after operation, but in each, miscarriage was imminent at the time of operation; three showed signs of impending miscarriage previous to operation which subsided after the removal of the tumors. Six women had extra-uterine pregnancies at the time the myomectomy was performed; in all, rupture had already occurred, with large pelvic hematoceles, one with a dead fetus of four and one-half months. The myomectomies and the operations for the extra-uterine pregnancies were performed at the same time in these six cases; it seemed possible that the presence of the tumors was responsible for the ectopic pregnancies. One of the patients has since borne a child.

It has been asserted that frequently tumors develop after myomectomy. Nineteen of these 741 patients (2.56 per cent.) required secondary operations; in eleven cases the operation was performed five or more years after the myomectomy, and in one, thirteen years afterward. One of the nineteen patients had a child after myomectomy. The majority of the secondary operations were performed for inflammatory disease. It was difficult to obtain accurate pathologic data of secondary operations, since more than half were performed elsewhere; but none of the patients had developed malignant disease. In many of the cases in which the second operation was performed for recurrence of the fibroids, the operation could today be avoided by the use of radium. In none of the cases reported were the recurring tumors large, because the patients, being aware of the former condition, were on the alert. Hysterectomy was usually performed, because the patient had been carried along by the myomectomy to the age in which a radical operation is of less importance.

In many cases of myomatous disease it is not possible to save a uterus that will bear a child; but in cases otherwise suitable, one ovary and enough of the endometrium can be saved to continue the menstrual function. I have removed all of one wall of the uterus and one ovary and tube and made plastic restoration; the patients have continued the function of menstruation normally for years.

In a former paper⁷ I noted the removal, by myomectomy, of a large tumor which had grown from the cervix. In the process of removing the growth, the fundus of the uterus was completely separated from the cervix and vagina, but I was able to anastomose the uterus to the cervix with catgut sutures with perfect results. I have had one other case of the same kind. If the patient has had hemorrhages and a myomectomy is performed, the endometrium should be opened, inspected, and thoroughly curetted under the eye. In my earlier cases I did this with a good deal of hesita-

tion, fearing to infect the uterine wound; but no such infection has occurred. The endometrium covering a submucous fibroid is atrophic. Cancer begins in the hypertrophic mucosa in the vicinity of the tumor, and the danger of cancer of the body of the uterus is increased by fibroids. In 1919, in an examination of 4,000 specimens of myomas of the uterus in our surgical museum, Evans⁸ found seventy-two malignant and related nonepithelial tumors of the uterus, thirteen definitely and eleven potentially sarcomatous, and forty-eight cellular tumors with malignant possibilities. He showed that by counting the mitotic figures in the cell nuclei, the chances of cure could be predicted; the giant cells are probably a defense and not a malignancy. The sarcomatous growths may be multiple; they are yellowish rather than glistening white, and on section they are softer than fibroids, and do not enucleate readily. The careful surgeon seldom makes the mistake at the operating table of believing them to be myomas and attempting myomectomy. If so, the frozen section will demonstrate the error before the operation is completed.

Radium must justly be considered, in selected cases, a competitor of hysterectomy, but it has no competitive standing in cases suitable for myomectomy. When bleeding necessitates interference in the menopause period, radium has a remarkable field of usefulness. If the tumors are large, coming well up into the abdomen, and are caused to disappear by the use of radium, the menopause is brought about. Massive doses of radium usually destroy the function of the ovaries and uterus, leaving these nonfunctioning organs to await an uncertain future. We must sharply distinguish between nonoperation and conservation. Radium may be even more destructive than hysterectomy, as in 50 per cent. of hysterectomies one ovary, and in 25 per cent. both ovaries, can be saved. It must be remembered, too, that at middle age 12 per cent. of white women and 30 per cent. of colored women have myomas. Every surgeon has observed, over long periods of time, women with multinodular myomatous uteri who have had no symptoms, and often have raised families. The mere presence of small to moderate sized, symptomless myomas that can be watched by physicians does not indicate operation, or treatment of any kind; many are now having radium treatment. I am convinced that this is not wise. While menstruation usually returns within a few months, it may fail ever to reappear even after the use of a moderate amount of radium.

HYSTERECTOMY FOR UTERINE MYOMA

I believe that total hysterectomy is a wise procedure if it can be performed safely, and usually it can. Leaving the cervix leaves an average cancer liability. We have seen twelve cases of cancer occur in the left-over cervix after supravaginal hysterectomy. Removing a cone of mucous membrane of the cervical canal from above, or plunging the cautery through the cervical canal to destroy it, is not sufficient. Peterson⁹ has shown that only one third of the cancers of the cervix begin in the cervical canal (adenocarcinoma). Two thirds of the cervical cancers are epitheliomas

9. Peterson, R.: Age Distribution and Age Incidence in Five Hundred Cases of Cancer of the Uterus, Surg., Gynec. & Obst. 29: 544-553, 1919.

originating in the vaginal parts of the cervix. After total hysterectomy, the patient seldom complains of local trouble. If the cervix is left, however, a foul, irritating leukorrhea sometimes results from degenerative changes in the mucous glands of the cervix. Shrinkage of the vagina appears to be greater after subtotal than after total hysterectomy. It seems as if nature, in the effort to shrink the cervix following supravaginal hysterectomy, is stimulated so greatly as to increase the shrinkage of the vagina as well.

Russell¹⁰ has called attention to the advisability of opening the abdomen, drawing up the uterus, and opening the anterior wall to expose the endometrium for examination in certain cases of prolonged uterine hemorrhage without apparent good cause. Since Russell's observation we have had occasion to do this twenty-six times in young women, and thus have been able to save the uterus. I have found polyps in one horn, which could not be reached with the curet, and small submucous fibroids. In a young woman who has hemorrhages from uncertain cause, exploration of the cavity of the uterus through the abdomen is preferable to radium, and should precede hysterectomy in doubtful cases.

CONCLUSION

I would reiterate that conservation of the menstrual function is of the utmost importance even if pregnancy is not possible, and that the surgeon who faces the necessity of removing the uterus or the ovaries, and the bringing about of all those endocrine changes attending the procedure, is taking a serious responsibility which must not be assumed lightly. The heredity of the patient is responsible for the nervous instability, but the operation may be the match which lights a fire, in the ashes of which the patient finds herself unable to readjust her life to her living condition.

ABSTRACT OF DISCUSSION

DR. C. JEFF MILLER, New Orleans: I am in accord with Dr. Mayo regarding the conservation of menstrual function, and the necessity of a more conservative attitude toward pelvic pathology. The thoughtful surgeon hesitates to remove ovaries unless they are hopelessly diseased, but we are just as radical in the treatment of fibroids of the uterus. Removal of the uterus is as radical, so far as function is concerned, as removal of the ovaries, and is equally as distressing to the patient. I agree with Dr. Mayo that myomectomy can be performed in many cases in which hysterectomy usually is done. I have had a sufficient number of pregnancies result after myomectomy to prompt me always to review a case with the view of performing myomectomy in preference to hysterectomy. We were formerly taught that myomectomy carried a slightly higher mortality rate than supravaginal amputation, chiefly owing to the risk of hemorrhage and occasional infection when the uterine cavity was opened. Later statistics will show that this was a defect in technic which has been overcome. During the past four years, I have performed more myomectomies than formerly, for the reason that if myomectomy failed to control excessive bleeding, radium could be used to complete the cure without the necessity of a second operation. In some case I have removed the entire musculature, preserving enough of the mucous membrane to conserve menstruation. Several patients developed a metrorrhagia, and sometimes menorrhagia which required further treatment.

Dr. Mayo is also correct in stating that total hysterectomy is preferable to a supravaginal amputation. If the proper technic is followed, total hysterectomy requires no more time, there is no greater risk of postoperative hemorrhage, and

convalescence is decidedly smoother. I have employed radium in the treatment of fibroids for six years, and I am enthusiastic as to its results in properly selected cases. But, until we know how much permanent damage is done by radiation, we should consider its use in young women as being probably more radical than myomectomy. I advise myomectomy for all young women, especially if the growth is a single one. It is necessary to produce an amenorrhea in order to cause shrinkage of a fibroid, and as yet we cannot gauge the dosage with sufficient accuracy to warrant its indiscriminate use in young women. As to the management of cystic ovaries: surgeons do not follow up their cases if they continue to resect ovaries. Only in exceptional instances should ovaries be resected. As a rule, the ovary is sufficiently involved to justify its removal, or it is healthy enough to let alone. In certain cases of serious pelvic infection where both tubes are removed, and the ovaries are involved to such an extent that it is not safe to leave them, transplantation of portions of an ovary will preserve menstruation for an indefinite time, or sufficiently long to allow of a gradual menopause without the uncomfortable results that so frequently follow abrupt cessation.

DR. JOHN O. POLAK, Brooklyn: Five years ago I reported the end-results of conservation of menstruation in connection with conservation of ovarian function. My observations are in accord with Dr. Mayo's: Ovaries are either damaged or not damaged beyond chance of regeneration. Most of the damage produced in these ovaries is due to the circulatory disturbance which is produced by the associated lesions. When this is corrected these ovaries regenerate themselves, and the so-called multicystic ovary, as large as a walnut, prolapsed in the pelvis, does not necessarily need to be removed. They have been removed only because of lack of knowledge of the pathology. Furthermore, it takes more than the leaving of an ovary to satisfy a woman that the psychic effect of the actual occurrence of the bloody discharge had a great deal to do with the comfort or discomfort of the woman. Where possible, it is advisable to retain a portion of the uterus, with its uterine mucosa, or when leaving a portion of the ovary, or even both ovaries. In cases of fibroid tumors, when the uterus is removed, leaving an ovary or both ovaries, the variations in blood pressure studies are higher than in those cases in which a portion of the uterus is preserved which produces a balance in the ovary and the other internal secretions.

DR. ROBERT T. MORRIS, New York: Conservation of the menstrual function has been overlooked in our zeal to do the right thing for the patient. Conservation of the menstrual function may often be obtained by ovarian grafting—when we remove an ovary in a mass with other structures, if a part of the ovary be placed back anywhere within the patient's economy. The time is coming doubtless when we shall be able to do heteroplasty. The heterograft is destroyed by antibodies and we may be about to make antibodies to meet these antibodies. We are just about on the verge of knowing something about that subject. Many men have argued in favor of the entire removal of the uterus in cases of Neisserian infection with its terminals. Why cannot we sometimes in confidence tell the patient frankly and fearlessly every feature of her case? Tell her the dangers of leaving a part of her uterus, the possibilities of a pregnancy if we leave the uterus, or the larger part of it. The day has passed when we cannot lay our problems before our patients.

DR. ALBERT J. OCHSNER, Chicago: I agree with Dr. Mayo. There is, however, this feature to be borne in mind. Some years ago I had charge of the surgical material in a hospital in which there was practically always reinfection in cases operated for pelvic infection unless the uterus was removed. At present there is practically never a reinfection because the patients belong to an entirely different social group. In the one case the hospital was supported by the wealthy women of the city and many of the patients treated there did not earn an honest living but depended on vice and charitable citizens. At the expense of these good people they were put into condition to take up again their

10. Russell, W. W.: Remarks on the Treatment of Tuberculosis of Uterus and Fallopian Tubes, *Ann. Surg.* 28: 468-471, 1893.

vicious service and they were practically certain again to become infected. In that class of patients in our city hospitals and in the hospitals supported by charity the menstrual function should be abolished by the removal of the uterus. So far as the difference in the mortality between hysterectomy and myomectomy is concerned, I have found that many of the deaths are due to pulmonary thrombosis. The percentage of pulmonary thrombosis in these cases varies from 0.1 per cent. to 2 per cent. The pulmonary thrombosis is very largely due to the lack of perfect hemostasis. Some years ago Kelly pointed out a simple method of securing hemostasis in myomectomy by placing one suture 1.5 cm. beyond either end of the incision in the uterus. Several years ago Professor Bue of Montevideo pointed out the fact that by placing a purse string suture over the entire field at the conclusion of a hysterectomy, whether this be a supracervical or a complete hysterectomy, the same result is obtained—no hemorrhage, no blood clot, no raw surface, a perfectly dry wound. This one feature reduces the mortality from pulmonary thrombosis enormously.

DR. WILLIAM J. MAYO, Rochester, Minn.: The discussions indicate that general surgery interests all surgeons engaged in the surgical specialties, and that the so-called gynecologist is simply a general surgeon who limits his work but not his interests. About twenty years ago, Dr. Ochsner told me that if I did not tie my ligatures so tight in my myomectomies, I would not have any postoperative trouble. I followed his advice and did not again have cause to worry over these unfavorable symptoms.

SPONDYLITIS AND ABDOMINAL PAIN

WITH A DISCUSSION OF NERVE-ROOT SYMPTOMS
SIMULATING VISCERAL DISEASE *

DOUGLAS VANDERHOOF, A.M., M.D.

Professor of Medicine, Medical College of Virginia

RICHMOND, VA.

Disease involving the articulations of the spinal column has occurred in human beings since remote times, as shown by examinations of Egyptian and Nubian remains dating back as far as 4000 years B. C. In addition, present-day postmortem investigations indicate that arthritis of the spine is not at all infrequent. In spite of these facts, one is distinctly impressed by the small number of cases that have been reported in the literature. Guffey,¹ in 1905, was able "with considerable difficulty" to find reports of only 131 cases of osteoarthritis of the spine. McCrae,² in 1909, reported a series of eighty-one cases of spondylitis secured from the records of patients in the Johns Hopkins Hospital, together with a number personally observed elsewhere. In the last few years, however, the extensive employment of roentgen-ray examinations has emphasized the frequent occurrence of spondylitis. The orthopedist has taken prompt cognizance of these roentgen-ray studies of the vertebrae, and by him the condition is regarded as a rather common affliction. It is a question, however, whether the internist and the surgeon also realize the incidence of spondylitis and its definite relation to clinical problems.

In the last seven years (1913-1919) the diagnosis of hypertrophic spondylitis has been made in eighty-

seven patients seen in my consulting room, and other instances of this condition have passed through my clinics in the hospitals and outpatient department of the Medical College of Virginia. I must confess that somewhat over half of the private cases have been recognized in the last two years.

Of this series of eighty-seven cases of spondylitis, forty patients complained of abdominal pain. In seventeen of these forty cases, the presence of visceral disease could be demonstrated, and the rôle played by the spondylitis was either questionable or negligible. In twenty-three patients, however, careful and complete studies seemed to exclude visceral disease as the cause of the patients' complaints. These twenty-three cases of spondylitis form the basis of this article.

The production of pain in spondylitis varies according to the extent and location of the inflammatory process in the spinal joints. This arthritis is frequently associated with hypertrophy of bone, atrophy of cartilage, and calcification of ligaments. As a result, there may be pain and muscle spasm in the back, limitation in the movements of the spine, and the gradual development of rigidity. If the arthritis involves the articulations of the ribs with the vertebrae there is likely to be severe pain on breathing, or even complete absence of thoracic respiration. Of particular interest, however, is the involvement of the nerve-roots by extension of the inflammation or by direct pressure of the exudate and new-bone formation.

Pressure on the nerve-roots in spondylitis, or their involvement by extension of the inflammation, gives rise to more or less pronounced sensory disturbance, characterized by pain in the distribution of these nerves. This pain may be perceived in the back, shoulders, hips or extremities, or it may be referred to the thorax or abdomen. The character of the pain varies greatly from a dull aching or drawing sensation to the most agonizing paroxysms. Certain patients with spondylitis suffer little or no pain in the back and make absolutely no mention of stiffness or other disability, while the referred symptoms may be pronounced. The thoracic, abdominal, brachial and sciatic pains of spondylitis may occur on one or both sides of the body; if bilateral, however, they are generally more severe on one side.

The referred pains of spondylitis are increased, as a rule, by movements of the body, especially walking, stooping or bending, and are promptly relieved by rest in the recumbent posture. In other instances the pain occurs in the night after the patient has been sleeping, and is attributed to relaxation of the accompanying muscle spasm, which acts as a guard or splint against sudden movements in the waking hours. Spondylitis occurs occasionally in persons who complain of no symptoms, either local or referred.

The involvement of the nerve-roots in arthritis of the spine was emphasized by some of the earliest writers on the subject. In fact, the preponderance of nervous symptoms in certain cases led von Bechterew, in 1892, to separate a special type of spondylitis, characterized chiefly by referred symptoms, such as pain, paresthesia, muscular atrophy and paralysis.³ That he regarded this syndrome as primarily a nervous disease, with secondary involvement of the spine, is now only of historical interest.

* Read before the Section on Practice of Medicine at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

2. McCrae, Thomas: Osler's Modern Medicine, Philadelphia, Lea & Febiger 5: 534, 1909.

3. A discussion of von Bechterew's views, together with a good account of the pathologic and neurologic features of hypertrophic spondylitis, is given by Rhein, J. H. W.: Pathologic Report of the Nervous System in a Case of Spondylose Rhizomelique, J. A. M. A. 51: 463 (Aug. 8) 1908.

The fact that the nerve-root pains of spondylitis may simulate visceral disease is quite obvious. That actual confusion in diagnosis may occur, however, is not generally recognized. After a somewhat detailed search of the literature I have been able to find only five references to such a contingency. Chute,⁴ in 1904, reported five cases of arthritis of the spine with referred pains imitating lesions of the kidney, prostate or seminal vesicles. Smith,⁵ in reporting sixteen cases of spondylitis in 1907, mentioned that one patient had undergone appendectomy for the relief of abdominal pain, which was subsequently shown to be due to the referred nerve-root pains of spondylitis. In 1912, Dickson and O'Neal⁶ gave the histories of three patients who suffered from both visceral disease and vertebral arthritis. In each instance, operation was performed, with removal of gallstones in one case, a kidney stone in a second case, and the repair of perineal lacerations in the third case. The persistence of symptoms in each patient led to the subsequent discovery of spondylitis. In two of their cases the nerve-root pains were acute and similar to tabetic crises. In their conclusions they emphasized the fact that "no examination (of a patient) is complete without a careful inquiry into the condition of the spinal cord and spinal column." Recently Allan and Squires⁷ have reported two cases of spondylitis, in one of which the patient was subjected to a laparotomy for supposed gallstones. Finally, a good discussion from the roentgen-ray standpoint is contained in the recent article by Blaine.⁸ This author lays particular emphasis on the fact that nerve-root pains may exactly simulate the acute suffering of renal lithiasis. The article is illustrated with roentgenograms of three patients with spondylitis in whom the clinical diagnosis of renal calculus had been made.

ILLUSTRATIVE CASES

As mentioned above, out of a series of eighty-seven personally observed spondylitis cases there were twenty-three patients who complained of abdominal pain, in whom visceral disease could apparently be definitely excluded as the cause of their suffering. In order that this report may not be too lengthy, I have abstracted below the histories of six of these cases. In Case 1 the roentgenogram of the spine showed no gross changes. The clinical findings were typical, however, of acute arthritis, secondary, apparently, to a pyogenic infection of the skin. The nerve-root pains were of a most severe character in Cases 1, 4 and 5, while Cases 3 and 6 illustrate the vague abdominal distress that may accompany arthritic changes in the spine. Cases 2 and 4 were subjected to laparotomy, with only a postoperative discovery of the spondylitis. Surgical treatment had been advocated in Cases 1 and 5 prior to the establishment of the diagnosis of vertebral arthritis. A seventh case, recently seen in my clinic at the Virginia Hospital, is reported because of its extraordinary interest. In all the clinical material at my disposal, both private and institutional, referred

pains due to spondylitis have been much more frequently encountered than the visceral crises associated with tabes dorsalis and other organic diseases of the spinal cord itself.

CASE 1.—Clinical Summary: Severe pain in left back and flank, with acute exacerbations imitating renal colic; urine negative; two roentgen-ray examinations revealed no calculi in urinary tract; roentgen-ray examination of spine also negative, but clear clinical evidence of spondylitis; complete relief followed orthopedic treatment.

History.—Mr. W. (3575), aged 17, student, seen Jan. 21, 1913, whose complaint was pain in the left flank and back, had been in very good health, with no history of acute infections until the summer of 1911, when he began to suffer with boils, which had been very troublesome. He was weak and had felt bad ever since the furunculosis started. Oct. 11, 1912, he was suddenly seized with an agonizing attack of pain in the left flank, for which he was given large amounts of whisky and three hypodermics. He was at school in North Carolina at the time, and his attack was considered to be kidney colic. The urine was examined and was said to show no albumin, pus or blood. He had no urinary disturbances except that he believed he passed an excessive amount of urine. He had no herpes. For five weeks after this acute attack he suffered with more or less pain in the left back and flank, and had some nausea. Roentgen-ray examination during this period disclosed no renal calculus. Jan. 16, 1913, he had a second similar acute attack and was given six hypodermics. He said that his back had continued to hurt; also that he could not walk or run well because of increasing the pain. He had had pains beneath the costal borders on both sides of the body, also pain across the small of the back about as severe on one side as the other.

Examination.—Complete physical examination was negative, except as follows: The skin showed considerable acne, and there was general abdominal tenderness, more marked on the left side. The patient handled himself stiffly. The lower dorsal and lumbar spine was very tender and showed marked restriction of motion. There was no kyphosis or scoliosis. The slightest jarring caused pain in the back. The reflexes were normal.

Examinations of the blood and urine were negative.

Stereoscopic roentgenograms of the spine disclosed no gross disease. Roentgenograms of the urinary tract revealed no evidence of calculus in kidneys, ureters or bladder.

Course.—The patient was referred to the orthopedist, who concurred in the diagnosis of acute arthritis of the spine with root pains. Under appropriate orthopedic treatment the patient was promptly relieved of his pains, and subsequently went on to a complete recovery.

CASE 2.—Clinical Summary: Sharp pain in abdomen when up and about; one attack of acute pain in left hypochondrium; patient's back overlooked in examination, as were also significant findings on roentgenograms; operation and removal of grossly diseased appendix; persistence of pain and post-operative discovery of marked spondylitis.

History.—Mrs. P. (5590), aged 70, seen March 5, 1915, whose complaint was abdominal pain, had always enjoyed good health, and there were no facts of special interest in the past history. The present illness began about one year before with pain across the back at the waistline. She soon developed, sharp pains in the abdomen around the navel and radiating to the back. These pains occurred when she was up and about or when she tried to move. She had had one attack of sudden acute pain in the left hypochondrium, associated with vomiting. This required morphin; otherwise she had had no opiates. In addition, the patient complained of pain in the neck and in the right shoulder, increased by moving the arm. She said she was comfortable when lying still, but on trying to move she developed pain through the abdomen and back. She had some sour stomach and much flatulence. Her bowels were constipated and the stools occasionally were light in color. She had had no jaundice.

Examination.—Physical examination was negative, except as follows: The patient was very thin; the systolic blood

pressure was 160 and the diastolic 106; the abdomen was retracted, with thin walls, shadows of the intestines being visible, and the superficial veins distended. An irregular mass was present in the right flank (thought to be either a tumor of the kidney or ascending colon, or possibly a Riedl's lobe of the liver). No note was made of examination of the spine.

The hemoglobin was 65 per cent.; otherwise blood examination was negative. A specimen of catheterized urine showed a heavy cloud of albumin, with an occasional leukocyte and hyaline cast.

Roentgen-ray examination of the urinary tract was negative. The liver was noted to be enlarged or displaced downward, but no mass was shadowed in the right flank.

On surgical consultation, exploration was advised, with the expectation of finding chronic cholecystitis with enlarged right lobe of the liver, or possibly malignant disease. Operation, March 10, 1915, disclosed a grossly diseased appendix that was adherent to a displaced right kidney. The gall-bladder, stomach and pelvic contents were normal.

Course.—After convalescence from her operation the patient experienced a return of pain in the abdomen and back as soon as she attempted to sit up. The original roentgenograms were again studied and disclosed slight evidence of hypertrophic arthritis of the lumbar spine. A second roentgen-ray study was then made of the dorsal spine and disclosed marked hypertrophic spondylitis with almost complete obliteration of the disk between the eleventh and twelfth vertebrae. The orthopedist reported distinct rigidity of the spine, with restricted motion, pain, etc. Because of the patient's advanced age he recommended symptomatic treatment and rest in bed on a firm mattress, rather than any attempt at fixation.

CASE 3.—Clinical Summary: *Vague, distressing abdominal pains, characterized by drawing, pulling and burning sensations; no acute pain, but the patient had had a "catch" in the left hip radiating to the lower abdomen; visceral disease apparently excluded; spondylitis not suspected, but found on making roentgen-ray examination of gastro-intestinal tract.*

History.—Mrs. W. (8423), aged 59, occupation a housewife, seen, Jan. 10, 1918, whose complaint was pain in the abdomen, had had malaria years before, pleurisy twenty years before, and rather frequent tonsillitis as a younger woman, but no other acute infections. She had had two children, and no miscarriages; the menopause occurred at the age of 43. There was no history of pelvic disturbances.

The patient dated the onset of her present illness to one year before, when she began to suffer with discomfort in the lower abdomen. For the last two years, however, she had had a frequent "catch" in the left hip, running across into the "bowels." The abdominal discomfort had gradually increased, and she described it as "a hard hurting and burning." She said that the intestine seemed to pull and draw, and she felt as if there were a knot in her bowels. She occasionally had pain between the shoulders and down the spine. Her appetite was good and she had no digestive disturbances, except constipation. While her pains bore no relation to meals, yet she had attributed them to indigestion and had restricted her diet; she had become weak and had lost about 35 pounds.

Examination.—The patient was thin and appeared to be weak; she had considerable pyorrhea, but the throat appeared negative; the abdomen was held rather stiffly and showed distinct tenderness in both iliac fossae. The spine was noted to be straight, with tenderness on pressure just to the left of the lumbar spine. No mention was made of the movements of the spine. Physical examination was otherwise negative.

The blood, urine, gastric contents and Wassermann test were negative.

Roentgen-ray studies of the entire gastro-intestinal tract (barium meal and barium enema) were negative. On certain of the plates, however, the lumbar spine showed marked evidence of spondylitis deformans.

Course.—The patient was referred to the orthopedist, who confirmed the diagnosis of spondylitis with root pains. After preliminary rest in bed she was treated with fixation by a plaster cast, with marked relief from her symptoms.

CASE 4.—Clinical Summary: *Recurring attacks of pain in lower left abdomen for over seven years; appendectomy and freeing of kink in sigmoid appeared to afford relief for one year; recurrence of symptoms; second study of patient disclosed arthritis of lumbar spine; pain controlled by fixation.*

History.—Mr. C. (10050), aged 49, a salesman, seen Aug. 25, 1919, whose complaint was pain in the lower left abdomen, had an attack of very severe "inflammatory rheumatism" at the age of 6 years and one attack of gonorrhea complicated by urethral stricture when 21 years old. There was no history of syphilis or of any other acute infections.

The patient first consulted us in July, 1913, complaining of attacks of pain in the lower left abdomen, together with indigestion. He said that he had had seven attacks of "acute indigestion" in the preceding eighteen months. These were characterized by agonizing pain in the lower abdomen, worse on the left side. The attacks were followed by pronounced abdominal soreness, confining him to bed for two or three days. He had some nausea and vomiting with his acute attacks, attributed to morphin that had been administered. His appetite was poor, and he complained of a frequent knot in his throat, but he had no flatulence or constipation. His attacks were likely to be followed by constant aching pain low down in the left abdomen. He stated that two roentgen-ray examinations of the urinary tract were negative and that the urine was reported to be normal.

Examination.—Complete physical examination (in 1913) was negative, except that the tonsils were enlarged and ragged, there was tenderness on palpation over the sigmoid and also tenderness over the head of the cecum, with pain on pressure which radiated toward the navel. Rectal examination was negative, but the spine was not examined.

The blood, urine and gastric contents were found normal. No further roentgen-ray examinations were made, but exploratory operation was advised. The opinion was expressed that the patient probably had diverticulitis of the sigmoid and possibly appendicitis. He was operated on through a median incision in July, 1913, and the surgeon reported that he removed a diseased appendix and freed a kink in the sigmoid.

Subsequent Course.—The patient returned to us in August, 1919, and stated that he had been relieved of symptoms for about a year following his operation. The pain in the lower left abdomen then returned. For the most part this had been a dull ache, but at times had been sharp and acute. He had also noted pains in the lower left back. These pains were increased on moving the leg, on stooping and on lifting. The pain disappeared when he sat still, but recurred as soon as he stirred about. No other symptoms of interest were noted.

Second Examination.—Complete physical examination was negative except as follows: The tonsils were large and ragged, there was receding of the gums with pyorrhea, and slight tenderness over the sigmoid. The spine showed scoliosis, with convexity to the right in the lumbar region, dorsal bowing with increased lumbar lordosis, tenderness on pressure in the lumbar region, restriction of motion on both flexion and extension, muscular spasm of the erector spinae group, and on lateral bending to the right, pain was produced in the left iliac region. There was no tenderness over the sciatic nerve, but the Kernig sign on the left was positive.

The blood, urine and Wassermann test were negative.

Roentgen-ray examination revealed osteoarthritis of the lumbar vertebrae, but no bony changes about the sacro-iliac articulations. Films of the teeth disclosed no apical infections.

Course.—The patient was referred to an orthopedist, who first put him at complete rest and then applied a plaster jacket. Several months later the patient reported practically complete relief.

CASE 5.—Clinical Summary: *Attacks of acute agonizing pain on left side resembling renal colic; frequent attacks of pain beneath the right costal border imitating biliary colic; considerable pain in precordial region; no pain in back; visceral disease apparently excluded; extensive hypertrophic spondylitis present.*

History.—Mrs. H. (10246), aged 47, housewife, seen May 23, 1919, whose complaint was pain in the upper right abdomen, had had occasional attacks of tonsillitis in the past, and the tonsils were removed in 1907. She had diphtheria as a child, typhoid fever in 1903, and influenza in October, 1918. She had had no other acute infections and gave no history of arthritis except some "rheumatic pains" in hands and knees. She had had four children and no miscarriages. Hysterectomy and appendectomy were performed in 1913. About fifteen years before the patient had recurring hematuria for six weeks. Nine years before she had a severe attack of apparent kidney colic, but she does not remember on which side. Her past history was otherwise negative.

The patient dated the onset of her present illness to four years before, when she began to have attacks of "acute indigestion," characterized by severe pain in the epigastrium and beneath the right costal border. These required hypodermics for relief, and were thought to be gallbladder colic. She had several such attacks in a year's time. In the last three years she had had no acute attacks, but had had almost constant pain through the lower right chest, at times quite severe in nature. In addition, during the last four years the patient had suffered from attacks of acute agonizing pain in the left lower abdomen, radiating from flank to groin and requiring morphin. She said she had a sore place in the lower left abdomen that was like an electric button. Touching this spot produced pain that radiated all over the left side of the abdomen. The preceding fall the patient weighed 138 pounds; her present weight was 118 pounds. Her history was otherwise unimportant.

Examination.—Complete physical and neurologic examination was negative except as follows: There was some tonsillar tissue present (incomplete operation); the mouth showed considerable dental work with some receding of the gums; there was slight diffuse abdominal tenderness, and definite rigidity of the spine in the dorsal and lumbar regions; there was hyperalgesia over the right lower thorax.

The blood, urine and gastric contents were normal. The Wassermann reaction was negative on blood serum and spinal fluid. The latter showed no increase of globulin, and gave a normal cell count.

Complete roentgen-ray study revealed lipping and hypertrophic bone formation involving the third to the ninth dorsal vertebrae and the third and fourth lumbar vertebrae, with almost complete obliteration of the intervertebral space between the third and fourth lumbar vertebrae. The gallbladder region, the urinary tract and the gastro-intestinal tract (opaque meal) showed no lesions; two alveolar abscesses were found in the mouth.

Course.—The patient was under observation in the hospital from May 24 to Aug. 7, 1919. For seven weeks she was kept absolutely in bed, and during this time was remarkably free from pain. She was then allowed to get up, preparatory to having a plaster cast applied. Shortly after this she was seized with a succession of most agonizing attacks of pain, radiating from the left flank to the groin. Specimens of catheterized urine examined immediately after these attacks showed no pus, blood or albumin.

The patient left the hospital wearing a cast applied by an orthopedist and went to her home in a distant city. Oct. 2, 1919, she reported in person and had a reinforced corset substituted for the cast. She looked well, had gained in weight, and had been entirely relieved of the severe pains in the chest and abdomen.

CASE 6.—Clinical Summary: Vague discomfort in lower abdomen described as pulling, dragging or taut sensations; periods of dull pain in epigastrium together with soreness in left chest and left hypochondrium; these symptoms occurred when the patient was up and about and disappeared when he rested in bed; no acute abdominal pain; no complaint of backache; visceral disease apparently excluded; spondylitis discovered accidentally during roentgen-ray study of gastro-intestinal tract.

History.—Mr. E. (10295), aged 49, farmer, seen June 5, 1919, whose complaint was indigestion, had "rheumatism" in the shoulders and arms four years before which disappeared after the extraction of certain teeth. He had influ-

enza in April, 1919. Otherwise he had had no acute illnesses and his habits were excellent; his wife had had twelve children and one miscarriage.

The patient dated the onset of his present symptoms to January, 1919, when he began to be troubled with a "taut" feeling in the lower abdomen. Shortly after this he had a slight fall, in a sitting posture; he suffered no immediate pain, but some hours later he had pain in the left side of the chest and abdomen, lasting fifteen days. In April he had a severe attack of influenza with fever for nine days and much hiccup. Following this the abdominal pain returned with marked soreness in the epigastrium and a pulling, dragging sensation in the lower abdomen, with occasional burning and flatulence. These symptoms were present every day. They were aggravated by walking about and were relieved by lying down, so that he had spent much of his time in bed. He said he could not bear any jarring of the body, and he had a tendency to hold the abdomen. His appetite was very good, and he had had no nausea, vomiting or sour stomach; but his bowels were constipated. He was about ten pounds below his usual weight of 160. Careful questioning elicited no other symptoms, and he made no complaint of pain in the back.

Examination.—Complete physical examination was negative, except as follows: The teeth were badly worn, with some pyorrhea; the brachial arteries were easily felt; the systolic blood pressure was 124; the diastolic 78; there was diffuse abdominal tenderness; the spine was straight, not tender, and showed stiffness and restricted motion, especially on lateral movements. Rectal examination was negative, and there was no hernia.

Blood, gastric contents, specimen of stool and Wassermann test were negative. The urine showed a cloud of albumin and a few hyaline casts.

Roentgen-ray studies were made of all the teeth, the urinary tract and the gastro-intestinal tract (immediately and six, twenty-four and thirty hours after eating, with screen and plates) and found negative. On two of the plates, however, a good view was obtained of the lower dorsal spine, and this showed a characteristic picture of hypertrophic arthritis.

Course.—This is not known; orthopedic treatment was advised.

CASE 7.—Clinical Summary: Severe pains in right side of abdomen extending from flank to groin and radiating to the leg; recently similar pains had developed on left side; patient had had two abdominal operations to secure relief, with removal of gallbladder and appendix; persistence of symptoms following operation; well marked evidence of spondylitis confirmed by roentgen-ray examination; visceral disease apparently excluded.

History.—Mr. M. (Virginia Hospital), aged 53, seen, Oct. 2, 1919, complained of pain in both sides of the abdomen. The patient's general health had been good. He had had a discharging ear as a child, and had malaria ten years before. There was no history of other acute infection, and he denied all venereal diseases.

The patient dated the onset of his present illness to an attack of pneumonia in May, 1918. On convalescing from this illness he began to suffer with sharp pain in the right flank and groin. This pain radiated to the back and also to the right leg. He described it as a dull, cutting pain, and he had taken a great deal of acetylsalicylic acid, which afforded some relief. At times the radiating pains had stopped, but he always had pain in the right groin. He had no pain on the left side until one month before. At that time lumbar puncture was performed and was followed by persistent pain on the left side similar in character and distribution to that on the right.

In December, 1918, the patient was operated on in a distant city and the gallbladder removed. In February, 1919, he was again operated on and the appendix was taken out. He was told that no definite disease was detected in either organ. About this time all of his teeth were extracted except three. There had been no change in the character of his pain, and the pains were no better and apparently no worse than they were at their onset. He had no definite

digestive disturbances, but was constipated. There were no urinary symptoms, and his history was otherwise unimportant.

Examination.—Complete physical and neurologic examinations were negative except as follows: There was moderate atheroma of the peripheral arteries, the systolic blood pressure was 120, the diastolic, 60; the abdomen showed two operative scars and diffuse tenderness, which was most marked in the lower right quadrant. The reflexes were normal. The spine showed moderate posterior bowing in the dorsal region, and marked rigidity and limitation of motion in the lumbar region.

Examination of the blood was negative except for definite secondary anemia; the urine showed a trace of albumin, a few pus cells and an occasional hyaline cast. The Wassermann reaction on the blood and spinal fluid was negative, and the latter showed no increase of globulin or cell count.

Roentgen-ray examination of the urinary tract was negative for calculus. Screen and plate study of the gastrointestinal tract (immediately and six and twenty-four hours after eating) was negative except for evidence of slight adhesions about the cecum. Plates of the spine revealed marked hypertrophic arthritis of the second to fifth lumbar vertebrae.

Course.—This is not known. The patient was advised to put himself under the care of an orthopedist.

In this series of eighty-seven cases of spondylitis, there were sixty males and twenty-seven females.

AGES BY DECADES

Ages, Years	Cases
From 10 to 19	1
From 20 to 29	4
From 30 to 39	7
From 40 to 49	21
From 50 to 59	25
From 60 to 69	21
From 70 to 79	8

No attempt was made to tabulate the age at onset of the spondylitis, as in many instances this was too uncertain.

As to the etiology of spondylitis, one is certainly correct in assuming that it is identical with that of arthritis in general. The vertebral localization of the arthritic process is no more peculiar than the involvement of other joints of the body. The relation of arthritis to focal infections is so definite in most instances that it would seem correct to suppose that the vast majority of arthritides are due to toxic absorption with special tropism on the part of the joints.

In this series of eighty-seven patients with spondylitis, three cases seemed to be consequent to typhoid fever and four cases appeared to be secondary to a gonorrheal urethritis. Nine of the patients gave a history of preceding acute rheumatic fever, and many of the patients had had one or more attacks of tonsillitis. While it may occur in young adult life, it must be recognized that, as a rule, spondylitis is comparatively rare before the fifth decade of life. Now, it is at the age of 40 years and beyond that focal infections about the teeth become manifest in many persons. In this personal series of spondylitis cases, pronounced alveolar infection was the rule in the majority of patients. The Wassermann test on the blood serum was made in sixty-two cases, and was negative in all these patients except one. In nine obvious cases the spine was not roentgenographed. Of the remaining seventy-eight cases, roentgen-ray examination revealed gross changes in sixty-eight and was reported negative in ten cases. From a consideration of all the possible etiologic factors in this series, I believe one is correct in

assuming that spondylitis may occur in early adult life as the result of certain infections, especially tonsillitis, acute rheumatic fever, gonorrhea and typhoid fever. In most instances, however, spondylitis is a disease of middle and late adult life, and is generally secondary to chronic focal infection about the teeth.

SUMMARY

The incidence of spondylitis, while familiar to the orthopedist, is not generally recognized by the internist and surgeon. The involvement of the nerve-roots in arthritis of the spine may give rise to referred pains not only in the shoulders, hips and extremities, but also in the chest and abdomen. The symptoms referred to the abdomen may simulate visceral disease, and may vary from vague discomfort to paroxysms of acute pain. In this series of eighty-seven cases of spondylitis, abdominal pain occurred in twenty-three patients in whom visceral disease could apparently be excluded as the cause. Errors in diagnosis lead to needless operations on gallbladder, appendix and urinary tract. Spondylitis with referred abdominal pain is much more frequent than tabetic crises. Relief of the nerve-root pains is secured by proper orthopedic treatment plus removal of responsible foci of infection.

ABSTRACT OF DISCUSSION

DR. GUSTAVE ROUSSY, Paris, France: [Dr. Roussy spoke in French. His remarks were translated into English by Dr. Thayer.] Professor Roussy calls attention to the similarity of the condition described by Dr. Vanderhoof, to certain observations made in France, in young men, who on roentgen-ray examination of the spinal cord showed rather extensive lesions, spicules, spines, and stalactite-like lesions of the vertebrae. He calls attention to the difference between two types of spinal arthritis, particularly that studied by Marie, and one beginning more commonly in the shoulder joint and in the hip joint, and resulting in extensive immobilization of the spine. The actual symptoms of immobilization are not striking but the symptoms of pressure come out markedly, without the evidences of grave immobilization. He mentions the circumstance that in the rhizometric spondylitis of Marie, he was rather of the opinion that in many instances the cause was gonorrhea. Three of the cases cited by Dr. Vanderhoof may be of that type, but in many of the cases of more benign spondylitis, Dr. Roussy is uncertain as to the cause. In some cases which they observed infection may have been the cause, but in many instances, there was no evidence that infection was at the root of the malady, and no apparent cause could be found. He calls attention to the similarity between these conditions and the interesting condition described by Madame Dejerine of a hypotrophic arthritis consequent on a severe wound, particularly about the knee and of the spinal cord. He mentioned that in several of those instances extensive ossification was observed in the abductor muscles of the thighs, extending for a very considerable distance down the thigh, a change ascribed by Madame Dejerine to some trophic injury to the cord. Dr. Roussy also called attention to the relative frequency of muscular atrophy associated with spondylitis, and spondylitis due to pressure. He calls attention particularly to a number of instances in which the sternomastoid, the trapezius and other muscles in the cervical region and in the region of the shoulder have been affected, in which, on careful roentgen-ray examination, distinct evidence of the cause has been found in the spondylitis.

SIR HUMPHRY ROLLESTON, London, England: I should like to express my surprised appreciation at the large number of cases which the author recognized. It is, indeed, rather remarkable that this connection has not been noted before, because, as many of you remember, many years ago John Hilton of Guy's, who wrote so much on "referred pain,"

pointed out that caries of the spine might cause abdominal pain, and it would appear that the mechanism in which spondylitis deformans produces symptoms simulating those of disease of the gallbladder, the appendix, etc., must be exactly the same.

DR. DOUGLAS VANDERHOOF, Richmond, Va.: The chief aim of my article was to emphasize the frequency of spondylitis. In recent years I have become especially impressed by the fact that arthritis of the spine is a very common condition. There is no reason why it should not be, when we consider the frequent occurrence of arthritis in general. We are often consulted by patients with peculiar girdle pains, underneath the costal borders. When on the right side, we may think of a diseased gallbladder. When the pain is on the left side, we are not so ready to diagnose a visceral condition. We have been able to demonstrate that certain of these persons have a localized spondylitis of the dorsal spine. One should remember that in making a roentgen-ray examination of the dorsal spine, a special technic must be employed. This paper contains the report of eighty-seven cases of spondylitis seen in the course of the past seven years, including 1919. I am sure that in the first three and a half months of this year I have seen twenty-five or thirty additional cases confirmed by roentgen-ray examination. This is important, because we must recognize the incidence of spondylitis, and we must also realize that some of these persons have referred nerve root pains that simulate visceral disease. Furthermore, we must bring these facts to the attention of our students in the same way as we have been trying to impress on them the importance of testing the pupillary reaction, the knee jerks, etc., to save the tabetic from needless abdominal operations.

SUBCUTANEOUS PHLEBECTASIS OF THE LOWER THORACIC AND UPPER ABDOMINAL REGIONS *

WILLIAM GERRY MORGAN, M.D.
WASHINGTON, D. C.

In the course of the routine examination of patients during the last twenty years I have noted here and there individuals presenting a peculiar dilatation of the cutaneous veins in the diaphragmatic area of the chest and upper abdomen. These veins stand out in an irregular wreath shape form, most often occupying the right diaphragmatic area, but occasionally the splenic area. In some instances the veins extend from one axillary line to the other and down each lateral aspect of the abdomen and across the hypogastrium, thus forming a complete wreath. There are two distinct types to be noted—those in which the dilatation is in the form of telangiectasis and those which are true varices. I have used the name "phlebectasis" to designate this affection.

This condition, in my experience, is vastly more often observed in men than in women; yet it does occur in women.

From the first time I observed this down to the present I have promised myself if an opportunity offered with a sufficient number of cases at my disposal, I would take up the study of this condition and attempt to learn its significance and causal relation. We have been taught to consider this as a sign-complex of embarrassed portal circulation, either from cirrhosis, malignant disease or hepatic abscess. Similar vascular nets occur in different parts of the body, but with nothing like the uniformity of formation or

the extent with which they are seen in the cases under consideration.

From my experience I am able to say that these varices are seen most frequently after the age of 30 and on up to 60 and even beyond. A definite cause of a more or less constant type must be present because of the constancy of type and the uniformity of arrangement and the constancy of location in the diaphragmatic area, and also, as I have pointed out, because of its greater predilection for men than for women.

It was necessary, in the study of this condition, to try to connect up the varices with the proper part of the vascular system, and if possible to determine whether or not the portal venous circulation was always concerned in it. This naturally has been a very difficult point to clear up, as I have never had the opportunity to have a study made at the postmortem table in one of these cases. If this point could be definitely cleared up it would pave the way for an elucidation of this entire condition.

That the condition is seen frequently in connection with cirrhosis of the liver would indicate that we must look to the portal circulation, near or remote, for causative factors in all of those cases in which no disease of the liver is to be demonstrated. This would lead us to search for causes elsewhere in the circulation even so far removed as the heart and the great blood vessels of the chest. We have also considered the action of the diaphragm in diseases of the chest organs in its relation to this condition. And finally a study of the nervous system in these individuals has been made in relation to its bearing on phlebectasis.

When there is any interference with the return of the venous blood in the direction of the heart, whether it is in the neighborhood of the superior vena cava or the inferior vena cava or the portal vein, either within or without the liver, there is an immediate attempt to establish the circulation of the blood by means of varices which, in the case under consideration, appear in the cutaneous circulation. Just why the deeper venous circulation does not entirely take care of the necessary collateral routes is not clear.

In looking for possible causes of the disturbed circulation in these cases we should consider compression of the vena cava resulting from an enlarged aorta from one cause or another, syphiloma of the mediastinum or of the lungs, pleuritic effusions, enlarged bronchial glands, cyst or cancer of the thyroid and even hyperthyroidism, and finally, thrombosis of the vena cava itself or of its branches.

Up to the present time, as I have heretofore remarked, we have not had the benefit of postmortem studies to aid us in determining the causative factors of this condition, which, to those of us who have observed it in individuals not suffering from the grosser forms of venous obstruction in this region, is its most interesting feature.

PATHOLOGY OF THE CONDITION

As I have not given sufficient study to this condition, I am not able myself to go more profoundly into the morbid anatomy of phlebectasis; therefore I shall quote at length from an article published in 1914 by Prof. M. Villaret.¹ Villaret gives the result of many years of study of subcutaneous phlebectasis. He has

* Read before the Section on Practice of Medicine at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

1 Villaret, M.: *Paris méd.* 15: 20, 1913-1914.

subdivided these varices according to their relation to the normal venous circulation. He goes on to say:

In order to simplify their readings, we have arranged schematic tracings showing the normal parietal circulation, noting on them the dilated veins observed and the direction of the current. From a large number of these tracings the following conclusions were drawn:

A. The circulation disturbance which affects the superior vena cava. The pathologic collateral circulation may be caused by compression of the superior vena cava, resulting either from aneurysm of the arch of the aorta, especially the first portion, cancer of the mediastinum or of the lung, syphiloma of the mediastinum, tuberculous tracheobronchial glands, old pleurisy, chronic mediastinitis, cancerous goiter, or even exophthalmic goiter. It may also be due to thrombosis of the vena cava or its branches.

1. Ordinary Topography: It seemed to us to be characterized by the following characteristics:

(1) Venous plexus localized over about one third of the chest.

(2) Usual dilatation of the long superficial thoracohypogastric veins of both sides, along their entire course, but especially about the thoracic segment.

(3) Frequent dilatation of the cervico-axillary vein.

(4) Notable absence of dilatation of the superficial median xiphoid vein.

(5) Reduction of supplementary plexuses.

(6) Direction of the venous current from above downward.

(7) Frequent concomitant edema of the face, neck, chest and arms.

2. Localized Forms: When the circulation disturbance is limited to a segment of the domain of the superior vena cava, or when it is quite limited, the superficial phlebectasis may be localized in the upper part of the body on one side, shoulder or arm or middle portion of the chest at the cervico-axillary vein.

3. Mixed Forms: When, on the other hand, venous stasis of the domain of the superior vena cava is accentuated, or is simply persistent, a time frequently comes when the foregoing circulatory type is modified. The partial plexus transgresses on the portal domain or on that of the inferior vena cava, and becomes too complicated for its reading to contribute to a serious etiologic diagnosis.

B. The circulatory disturbance is in the domain of the inferior vena cava.

(1) Localized venous plexus, or at least clearly predominating in the region of the infra-umbilical region of the abdomen.

(2) Habitual dilatation of the middle abdominal subcutaneous veins.

(3) Frequent extension of the abnormal vascularization of the superficial iliac circumflex veins, and to the middle portion of the long tegumentary thoracohypogastric veins.

(4) Decrease of the abundance of the supplementary plexuses, beginning with the inguinal cavity, where they arise, up to the costal regions.

(5) Absence of notable dilatation of the superficial median xiphoid vein.

(6) Direction of the venous current from below upward.

(7) Habitual concomitant edema of the lower limbs and sometimes of the external genitals.

2. Localized Forms: When the casual disturbed circulation is limited to a segment of the domain of the inferior vena

cava, or of limited extent, the superficial phlebectasis may become localized.

3. Mixed Forms: More often, during the second stage, the rapidity of the appearance of which depends on the degree of the obstruction, the preceding superficial vascularization surpasses the primitive limits, in order to encroach on the portal territory. We are then dealing with the cava-portal mixed types, currently observed but not clearly described. They are found in generalized tuberculous peritonitis of the sclerotic form, and of peritoneal cancers.

C. The circulatory disturbance occurring in the domain of the portal vein.

More interesting than the foregoing are the symptomatic collateral circulations of the syndrome of the portal hypertension. They follow diverse hepatic affections of the polyphlebitis opposing the normal current of the blood of the portal vein toward the suprahepatic veins.

The collateral circulation of the thoraco-abdominal wall is very frequent and particularly decided in the course of polyphlebitis of the trunk of the portal vein. They come on suddenly, if the venous obstruction is complete, or slowly and gradually if the thrombosis is simply parietal.

Just as frequent, but much less voluminous and of a more progressive development, are the cutaneous varices following cirrhosis, especially atrophic cirrhosis of Laënnec's type. They may be absent, especially in the case of anascitic cirrhosis.

1. Ordinary Topography:

(1) Beginning of the ectasis in the umbilical region, or, more rarely, in the linea alba, the collateral circulation of portal origin not being able to occur, excepting following dilatation of the venous system of the umbilicus, or of the neighboring perforating branches. Caput medusae constitutes a very decided degree of umbilical varix.

(2) Localized venous plexus, or at least decidedly predominating, in the neighborhood of the supra-umbilical and inferior thoracic regions.

(3) Habitual ectasis of the superficial median xiphoid vein.

(4) Frequent dilatation of the superficial long thoracohypogastric vein.

(5) Possible predominance of ectases in the neighborhood of the hypertrophied liver and spleen.

(6) Absence of noticeable varices in the neighborhood of the abdominal subcutaneous veins.

(7) Direction of the current being from below downward.

(8) Rarity of concomitant edema of the lower limbs and genitals.

2. Localized Forms: (1) The first variety is formed by the exclusively umbilical and periumbilical varices.

(2) The predominating ectasis of the xiphoid median vein and the perixiphoid plexus. Often it is combined with that of a long thoracohypogastric vein.

(3) The supplementary circulation of portal origin becomes apparent only in the neighborhood of the lower third of the thorax.

3. Mixed Forms: Often subcutaneous phlebectasis of cirrhosis undergoes variations from one period to another of the disease. The most important modification of the plexus of portal origin is when the cava type is added to it.

From the foregoing rather complete summary of the pathology of this condition, the etiology and development of cutaneous phlebectasis in the thoraco-abdominal region is more clearly to be understood.

Wreath of dilated cutaneous vessels in abdominal wall; taken from life.

OBSERVATIONS IN ONE HUNDRED CASES

I will now examine the clinical histories of the 100 cases which have come under my observation during the last five years, these being taken from more than 5,000 patients who were examined by me during that period, and which number certainly warrants some preliminary conclusions to be drawn.

In studying these cases individually I at first took note of every symptom and abnormal sign, however slight; but later, when considering them collectively, all those which clearly bore no relation to this condition were ruled out, and only those signs and symptoms which occurred with sufficient frequency to make it appear that they might have some significance were retained.

A summary of the tabulated findings reveals that out of 100 persons affected with phlebectasis, ninety-five were men and five women. The ages ranged from 24 to 82. Seventy-three were more than 40 years of age. Seventy-six were married and twenty-four were single. Fifty-eight led sedentary lives. Forty-two led active lives. Fifty-eight had prompt capillary circulation; thirty-seven had tardy capillary circulation, and in five the circulation was not noted. Seventy-two had normal radial vessels; sixteen firm, and twelve beady. In seventy the pulse rate was normal; in seventeen rapid, and in thirteen slow. The blood was normal in seventy-seven. Twenty-three were anemic. The blood pressure was normal in forty-seven; seventeen had hypertension; thirty-five had hypotension. The Wassermann reaction was negative in eighty-two, positive in nine, and not made in nine cases. The heart was normal in seventy-eight cases and diseased in twenty-two. The lungs were normal in ninety-one cases and diseased in nine. The liver was normal in seventy-one, and diseased in twenty-nine. The gall-bladder was normal in seventy-five, and diseased in twenty-five. The spleen was normal in ninety-eight, and diseased in two. Bowel action was normal in twenty-eight; sixty-eight were constipated; four had diarrhea. The urine was normal in eighty-seven, and abnormal in thirteen. The gastric juice was normal in forty-seven. Twenty-five had hyperacidity, nineteen, subacidity, and the condition was not stated in nine. The nervous system was normal in seventy-nine, and diseased in twenty-one. The gums were normal in twenty-seven, and diseased in seventy-three. Nutrition was normal in seventy-four, and poor in twenty-six. The roentgen-ray findings were negative in thirty-one, and were not made in twenty-one cases; in forty-eight cases they revealed some pathologic condition in the chest or alimentary tract, or both.

The past history was largely negative so far as this condition goes. Thirty-six had suffered from diseases which might have had some predisposing relation; fifty-four were entirely negative. Seventeen cases either gave a history of syphilis or had a positive Wassermann reaction. Seventy-five used tobacco; twenty-five did not. Eighteen used alcohol; eighty-two did not. Thirty-six suffered from organic diseases affecting the alimentary tract; twenty-nine, from organic diseases affecting exclusively the biliary tract; thirty-one, from organic diseases affecting the circulatory system, and nine from diseases of the respiratory organs.

RECAPITULATION

Phlebectasis of the cutaneous circulation in the lower thoracic and upper abdominal areas occurs

almost exclusively in men after middle life. Of the women affected, two suffered from endocarditis, one from syphilis, one from cholelithiasis, and one from hyperthyroidism.

The conditions which are most frequently associated with phlebectasis of the abdominal walls are constipation, disturbed arterial tension, oral infection, syphilis, heart disease, aortitis, diseases of the gall-bladder, diseases of the liver, and organic disease of the nervous system.

CONCLUSIONS

From this study of phlebectasis of the cutaneous circulation of the lower thoracic and diaphragmatic areas it has been impossible to discover the exact determining cause or causes for the condition. It can be definitely stated, however, that it is an accompaniment of more or less profound pathologic changes of the midbody which without doubt affects most probably the liver, the heart or the great blood vessels.

1624 I Street.

ABSTRACT OF DISCUSSION

DR. J. RUSSELL VERBRYCKE, JR., Washington, D. C.: Until Dr. Morgan called my attention to this peculiar purplish red capillary enlargement I paid little attention to it, regarding it as being accidental. Since then, however, I checked up my own cases, and found that this condition is characteristic. It occurs almost exclusively in males, and, as a rule, in adult life. Ordinarily, the patient is not aware of the presence of the condition. One man told me that he had had it since birth; but it is possible that he was in error. The form and distribution of these lesions is also characteristic. They seem to appear in order, most commonly over the liver, second, over the splenic area, then over both, and least commonly, in a semi-wreath shape, extending across the lower costal region, and down on each side. The cause, I am sure, is not to be found in any disturbance of the general circulation or of the viscera. The capillaries, and most of them are capillaries, are not enlarged enough to indicate any gross obstruction. These capillaries resemble those which run down over the edge of the nose in acne rosacea, and I am inclined to think that the same cause is operative in both instances. No one factor is sufficiently constant to warrant considering it etiologically. Therefore, the exact cause of this lesion still remains to be found.

DR. CHARLES F. HOOVER, Cleveland: This condition was described in the late 'eighties by the physician of Bismarck. He termed it a corona.

DR. LOUIS G. GENELLA, New Orleans: An Italian physician in Milan twenty-five years ago described this condition and illustrated it exceptionally well. He claimed that these abdominal varicose veins are all malignant, but that it is a very slow form of malignancy. He warned every surgeon, however, that whenever he opened an abdomen and found a marked varicose condition of the broad ligaments, to be assured that his patient would die within probably six or seven years.

DR. FRANK BILLINGS, Chicago: I became interested in this subject more than twenty years ago. Sir William Osler happened to be in my clinic when a very illustrative case of this kind was shown. He said that he had frequently found this condition in children and in certain persons of whose tissues it was characteristic.

I found that it did occur in persons who used alcohol, particularly beer, in excess. These dilated venules are at about the junction of the intercostals, the internal mammary and the epigastric veins. In cases of obstruction of the portal vein such varicosities do not occur at this site, or if they do, they are large vein dilatations. Or if there is obstruction of the superior vena cava, and consequent enlargement of the internal mammary veins, the enlargement is not like this. I cannot

accept Dr. Morgan's conclusions as an explanation of the dilatation of these venules.

DR. WILLIAM S. THAYER, Baltimore: Have you seen cases of like venules extending up the chest, all the way to the clavicle? I know of one instance, an active man, about 56, who has a line of them extending away up to his clavicle, along the costochondral articulation.

DR. WILLIAM G. MORGAN, Washington, D. C.: In a close study of between five and six thousand patients I never met a case in a patient less than 30 years of age. The definiteness of arrangement and location was characteristic.

I have seen one patient who had this condition extending up the chest. That woman had a widespread thickening of the lung on that side, for which no definite cause was assigned.

MEASLES: BRAIN COMPLICATIONS *

A. L. SKOOG, M.D.

KANSAS CITY, MO.

Even in a discussion of any neural complications or sequelae that might occur in a case of measles, we are compelled to admit and even bear in mind that the exact cause of measles still remains unknown. If the disease is studied from the standpoint of the epidemiologist or bacteriologist, the logical conclusion is that the etiology can be attributed only to some organism as yet unseen and uncultivated. Thus many investigators finally conclude that some ultramicroscopic organism is responsible.

We are forced to the conclusion that complications or sequelae, whether involving the brain, spinal cord or peripheral nerves, are uncommon. Yet they are probably of sufficient frequency, and certainly of sufficient gravity, to warrant a serious consideration. Surely we have no right to consider measles a simple and harmless affection.

Relative to the frequency of the neural disorders, I find that the recent literature bearing on this subject is not much more abundant than the ancient. According to Orthalan,¹ palsies following acute fevers were mentioned by Hippocrates and Galen; but the first allusion to measles in this connection was made by Olier in 1772, who referred to this disease as "a cause of acute hydrocephalus." H. B. Allyn² gives James Lucas credit for reporting the first case, in 1790, in the *London Medical Journal*. Of fifty patients seen in one epidemic in 1890 by Espagne,³ one died from a complicating meningitis with convulsions and lethargy. Wilhelm Möller⁴ reports on 537 deaths in an epidemic of 1887, this being a death rate of 3.72 per cent. Among the many complications, convulsions and aphasia were rare. There were five cases of meningitis, three being reported as simple and two as tuberculous meningitis. A few of the textbooks on nervous diseases and works on internal medicine mention in a line or two the brain disorders resulting from measles, but many make no record of the subject.

A study of the literature indicates that the brain complications and sequelae of measles occur much more frequently in children than in adults, and during the convalescence much oftener than during the febrile or exanthem stage. Thus a large percentage of the disorders might be classed preferably as sequelae than as complications.

A large variety of pathologic lesions is reported as involving the central nervous system during and following measles. However, most of the cases found in the literature may be grouped under three or four headings. The meningitis group has a larger number than any other. Thomas⁵ cites cases with meningitis, meningo-encephalitis, hydrocephaly, cerebral thrombosis, cerebrospinal affections, tuberculous meningitis, hemiplegia, apoplexy, hyperemia of the brain, and some others. Jürgensen⁶ would doubt the accuracy of the Thomas reports, questioning often the responsibility of the measles.

I am reporting two cases which may be classed as sequelae to measles, one a cerebellar and the other a meningeal involvement.

REPORT OF CASES

CASE 1.—*A cerebellar sequela.*—*History.*—W. L. W., a girl, aged 4 years, whose mother was well and had had no other pregnancies, and whose family and past history was negative, had always been a robust, healthy child. Teething, walking and talking occurred at the usual age. Measles was first determined by a typical macular eruption, Koplik spots, photophobia and other manifestations, Jan. 30, 1915. Eruption and acute symptoms were practically absent on the seventh day. About the twelfth day and during convalescence the mother noticed that the child did not use her hands quite the same, there being an unsteadiness when playing with toys or performing any voluntary act. The same state was seen soon in the lower extremities so that walking was impaired; and in a very short time she could hardly get about. There was an increased irritability, and some crying. Appetite and stools were normal.

Examination.—On the third day following the first neurologic manifestations, the general nutrition was fair. The temperature and the pulse were normal. There was a slight evidence of a past macular eruption. Cerebration was fairly good. The patient was inclined to be a little sulky or obstinate. The tongue was protruded mesially, but with much coarse tremor. There was a tendency to some nystagmoid movements when looking to the extreme right or left. Other cranial nerve findings were normal. The arms and legs had fair power for individual movements, there being no true palsies. Sensory tests gave normal responses. All deep reflexes were slightly increased, the right equaling the left. The superficial reflexes were normal. The movements in all the extremities were markedly ataxic, the right being the same as the left, but the arms slightly more than the legs. The voluntary movements of the hands were so ataxic that she could scarcely hold and drink a glass of water. The incoordination in the lower extremities made standing and walking quite difficult. There was no Romberg sign. All the incoordinations were typically cerebellar in type. Cerebellar asynergia was evident. Two days later not much change was to be noted. Ten days later a great improvement was found. Seven weeks after the onset of the neurologic sequel, almost no trace of the clinical signs of involvement of the nervous system was present.

I believe that in the case just cited we have had a pathologic process involving essentially the cerebellum. Possibly other portions of the encephalon were involved in a very minor degree. A complete recovery in a short period indicates that few or no cerebellar neuronal elements were destroyed. There was present an inflammatory process, either the result of an intoxication or directly from some secondary organism or from the hypothetic virus of measles. The termination precluded a necropsy. A spinal puncture was denied.

6. Jürgensen, Measles, in Nothnagel: *Encyclopedia of Practical Medicine*, p. 330.

The only parallel case has been found after searching the literature. A. W. Fairbanks,⁷ under the title "Ataxia Following Measles," cites a case indicating an involvement of the cerebellum during convalescence following measles. However, there were evidences of added involvement of the right motor neural tracts. E. Apert⁸ mentions a form "rougeole ataxo-adyynamique."

CASE 2.—*A meningitis complication.*—History.—L. H., a girl, aged 4 years, whose family and past history was negative, had been a healthy, well developed child. In July, 1919, I consulted with Dr. Frank Neff, who had taken charge of the case a few days previously, and about ten weeks after the attack of measles. There was present with the measles a bronchopneumonia. An otitis media followed. The child did not leave the bed after the measles and the subsequent complications. There was a state of marked helplessness, inability for any coordinated movements, and the child was inarticulate. Dr. Neff in his examination found a negative von Pirquet reaction; a white cell count of 5,400; a negative Wassermann reaction on blood and spinal fluid, and a spinal fluid clear, with no pleocytosis or bacteria.

Examination.—The patient was seen in bed, entirely helpless and speechless. She recognized no one. There was present much psychomotor unrest, with constant purposeless movements of hands and feet. There were no true palsies. There was some response to spinal stimuli. The superficial reflexes were present. The deep reflexes were present in the upper extremities, brisk at the right patellar and Achilles tendons, and feeble at the left. The Babinski and Oppenheim reflexes were questionable. The pupils responded to light and accommodation, but to a diminished degree. The eye grounds were nearly normal. Vision and hearing were undoubtedly present.

A neurologic examination in September indicated much improvement. Walking was possible.

A neurologic examination eight months after the first one indicated much favorable progress. The patient walked and played some and recognized her parents. She was unable to talk. Movements were not perfectly coordinated. Petit mal convulsions had been present during certain periods.

This patient undoubtedly had a meningitis with the other complications following the measles. The type of secondary meningeal infection was never determined. A cerebritis with a particular involvement of the cortex, as so frequently happens with meningitis, was evident. In the way of prognosis, it is reasonably certain that imbecility and possibly epilepsy will always be present.

THREE GROUPS OF CASES

In a concluding examination of the subject of brain complications and sequelae appearing in the course of or following measles, after a critical review of the reported cases and discussions in the literature and an analysis of my own few cases, I would make three groups:

1. The first group would include a certain minor number of cases in which the relationship of the measles would be merely incidental. Some of the cited cases have the onset of the brain troubles as first occurring several weeks to a few months following the eruption. Naturally the bearing of the measles infection to such sequelae can be questioned with justice. Of course, bacteria of various kinds may be harbored for a long period and under certain conditions be released as a local or general infection, when resistance in the host has been lowered by a disease such as measles.

2. The second group would include the secondary infections due to various organisms. The bacteria may be delivered to the central nervous system by the blood stream. However, the mode of invasion is undoubtedly in most instances through the cribriform plate from the nasopharyngeal cavities. This route of infection for *Diplococcus intracellularis-meningitidis* and the acute poliomyelitis virus is now well recognized. A great many more cases of meningitis follow measles, compared with all the other complicating disorders in the central nervous system. The fact that a large majority of the complications have their onset a few days following the disappearance of the eruption or during the early convalescence speaks for the importance of this second group. The interval is in accordance with the incubation period required for most of the organisms for secondary infections.

3. The third small group is a less certain one, owing to the fact that the exact etiology for measles is as yet undetermined. Clinical studies of the disease lead us to believe that the blood stream is teeming with the virus. Accordingly, the vascular channels of the meninges and brain may readily become involved. Certainly, some of the brain complications first manifested during the eruptive stage or the early convalescent period may be caused directly by the unknown virus of measles. Even some of the troubles appearing later in the convalescence may be due to this cause.

The prognosis for these brain disorders certainly depends on the brain tissue changes. If there has been much involvement of the leptomeninges or destruction of many important neurons, complete recovery is uncommon. From reports of good recoveries within from one to four months, I infer that the pathogenesis was mild. It was mild in my case with ataxia, which made a complete recovery in a few weeks; and severe in the meningitis case, in which entire recovery could hardly be anticipated.

The management and treatment of these cases depends on the lesions and the attendant deformities or deficiencies. Prophylaxis is first in importance. No unnecessary exposures to measles should be tolerated. Then the disease should be given careful attention, particularly as to preventing complications. Possibly many of the complications with meningitis reported might have been avoided had some attention been given the upper respiratory passages.

CONCLUSIONS

Cases of measles are sufficiently important to warrant careful consideration. Involvements of the brain in the course of measles, while apparently not as frequent as in other infectious diseases, are occasionally encountered. It is possible that many have not been diagnosed or recorded.

I have seen in my consulting practice and in the clinics of other neurologic consultants, certain mild neurologic or mental cases that were difficult to catalogue. This includes some with the neurasthenic syndrome. They may have originated from troubles in the brain or meninges in the course of or following measles and other exanthems. We can trace some of these neurologic disorders back to early childhood without knowing the exact etiology. I believe that at least a portion of these can be attributed to permanent pathologic residues in the encephalon or its leptomeninges, directly caused by the toxin or virus of measles or from one of the complicating secondary infections.

ABSTRACT OF DISCUSSION

DR. KARL A. MENNINGER, Topeka, Kan.: This paper furnishes additional evidence that we should not be too hasty in drawing a distinction between mental and physical forces. Until we know what feeble-mindedness really is, it behooves us not to be too arbitrary in regard to cases of feeble-mindedness being born and not made. Kraepelin advanced the theory that there is a faulty specificity in infectious diseases. My own work in influenza has tended to show something to the effect that instead of this sort of thing being faulty specificity, it is rather, a quantitative specificity. That is, whereas one physical disease would be accompanied by a single or rare mental complication, others would be accompanied by a great many complications. I do not believe that there is any specific psychosis.

DR. A. L. SKOOG, Kansas City, Mo.: We should be on our guard constantly when making neurologic examinations, especially in these cases in which the etiology is obscure and uncertain, to determine whether the actual cause of the disease may not rest in some long forgotten antecedent disease such as measles.

CONGENITAL FACIAL PARALYSIS

TWO ADDITIONAL CASES *

FRANK R. FRY, A.M., M.D.

ST. LOUIS

Dr. Michael Kasak and I¹ last year presented to the American Neurological Association the notes of a case of congenital facial paralysis of unusual interest. Two additional cases I believe deserve to be recorded, and I am therefore presenting them on this occasion. As a rather extensive bibliography accompanied our paper last year, I am omitting it here.

REPORT OF CASES

CASE 1.—Helen B., aged 1 month, was first brought to the pediatric service of the outpatient department of Washington University School of Medicine, Sept. 9, 1916. On physical examination it was evident that motility was absent in the lower right side of the face, and the upper portions seemed weak. The lower left side also seemed weak. The lower lip was everted to a considerable degree, and the right corner of the mouth was pulled down more than the left when the patient was crying. The upper lip seemed short and thin. The mother noticed the peculiar condition of the face the next day after birth, and stated that the child was not nursing well on account of it.

September 23, the patient was first examined in the neurologic clinic.

October 11, the child was first brought to the ophthalmic clinic with a slight conjunctivitis, which was improved after several visits.

March 23, 1917, the infant appeared in the otologic clinic. The examination revealed an acute otitis media on both sides, and both membranes were punctured. Within three days the acute symptoms had subsided. The patient was finally discharged from the otologic clinic as well, June 1, 1917.

Meantime the patient was seen from time to time by Dr. Michael Kasak and others in the neurologic clinic, until the time of her last recorded visit, Nov. 11, 1918. At this time Dr. Kasak and I examined her together. The child was then 27 months old. In repose, the mouth fell open with an eversion of the lower lip. The upper lip seemed relatively short. When crying, the right corner of the mouth drew down, making an unpleasant deformity. This was evidently due to the action of the platysma. The left side of the face also gave the impression of weakness, and especially when the

child was crying there was an evident lack of motility in the upper portions of the face as well as in the lower, more so in the right. The mother stated that the eyes did not close completely when the child slept.²

In all other respects, the child seems normal. The family history furnishes no items of importance. The labor was spontaneous and easy, and at full term.

This case was in the service of Dr. Sidney I. Schwab, chief of the neurologic clinic. He saw the patient only once, as he was absent in France in war service, during the time of her subsequent visits to the clinic. The child was 6 weeks old at the time of Dr. Schwab's examination. His impression then was that there was a peripheral paralysis of the seventh nerve only on the right side. He kindly accorded us the privilege of using the clinic's notes in our report. Later on, however, the conditions as we have described them were evident, and they recall certain observations of Vogt:³

In peripheral facial paralysis the whole side of the face is motionless; in central and in most of the bulbar (types) the superior branch retains its movement. In congenital cases the superior branch remains motionless, while the region about the mouth retains either complete or partial motility. When this difference between the upper and lower part of the face is great, it gives a characteristic facial expression: full, protruding lips which are in contrast with the masklike, expressionless, sunken face above. The appearance of the face makes the condition often recognizable at the time of birth, and gives one the impression of an advanced atrophy or aplasia of muscles; also, the skin over the muscles is usually smooth, peculiarly shiny and colorless.

CASE 2.—E. P. L., seen Sept. 2, 1919, had a very evident right facial paralysis, associated with other interesting phenomena, a description of which I shall give after that of the seventh nerve. I am reporting it here as a congenital condition on the grounds of the convincing statements of the patient, a very intelligent, refined and educated young man. Since his earliest recollections his face has had the peculiarities now present. These he recounted in detail. In careful conversations with his mother she had convinced him and others that the condition was congenital. She had further told him that her labor at his birth was normal in all respects. His mission to me was out of the ordinary. The father of his fiancée had asked him to furnish a certificate from a specialist that his facial condition was not hereditary in character. He had gone about this conscientiously and systematically, by first obtaining all the data he could concerning his family history, and then presenting it and himself to me for examination, coming a long distance in order to do so. This history contained nothing bearing on the case.

The right sided paralysis is evident in all portions of the face, but more so in the lower. In going through the usual test movements the corrugations of the right forehead are only slightly less than on the left side. The palpebral fissure is about equal on the two sides, but there is a retracted and fixed appearance of the right lids in contrast to those of the left. The pulling to the left is marked, causing considerable disfigurement. On the right the lips are slightly flabby, the lower lip being somewhat everted. The whole right side of the face has a thinner and more flabby look as compared with the left side, and this is more marked in the lower portion. The condition causes the patient no disability or inconvenience of any kind that he can mention. The function of the left seventh nerve seems to be wholly intact.

In addition to this right facial paralysis there is evidently some defect in both motor fifth nerves, or at least in some

1. Fry, F. R., and Kasak, Michael: Congenital Facial Paralysis, *Arch. Neurol. & Psychiat.* 2: 638 (Dec.) 1919.

2. Prior to this, Dr. Kasak had studied the case carefully, and he and I had expected to include the report of it in our paper on congenital facial paralysis presented to the American Neurological Association, June 16, 1919, but owing to an accident with the notes it was omitted. The credit of its preparation belongs to Dr. Kasak.

3. Vogt, H.: *Infantile Beweglichkeitsdefekte im Bereich der Hirnnerven*, Handbuch der Neurologie (M. Lewandowsky), Berlin, 1911, p. 270.

of the muscles which they serve. Both temporal muscles are attenuated, giving a sunken appearance to these regions, and the contractions under the finger are feeble compared with a normal subject. The right masseter, compared with the left, has an hypertrophied appearance. This is probably, partly at least, due to attenuated superstructures. The left masseter is deficient in bulk, especially the anterior portion of it. What there is of it, however, contracts forcibly, as does the right. The lower jaw is slightly shifted to the right, and tilted slightly upward on this side, so that the teeth do not articulate regularly. The line of the lower incisors is one-fourth inch to the right of the right of the upper ones. The lateral movements of the mandible, however, seem normal in range and strength, and the same seems to be true of its vertical force, notwithstanding the muscle defects just described. Dr. M. A. Bliss examined the patient with me and called attention to the fact that the platysma function was apparently entirely absent on both sides.

A phenomenon which greatly interested us was a very fine fibrillation, ranging in small waves about the face, almost constantly present in one region or another. This invades more or less all portions of the face below the lower eyelids and seems more pronounced on the right. The masseters appear also to be involved, especially at the acme, as it were, of the larger waves of the movement. The movements are so fine as to be noticeable only when rather close to the patient.

The musculature of all other portions of the body is thoroughly intact. When stripped, he presents a fine symmetrical appearance in this respect. The reflexes in all extremities are normal. He seems well and strong, and is very active. He was through rather intensive service for several months during the war. There is no disturbance in function of any of the ocular muscles, nor of any of the cranial nerves, except those here mentioned.

There are no sensory disturbances anywhere. Taste is not impaired on either side.

In view of these findings it would seem that the defects are nuclear.

TIDAL IRRIGATION OF WOUNDS BY MEANS OF LIQUID-TIGHT CLOSURE

W. H. TAYLOR, M.D.
GUELPH, ONT.

AND

N. B. TAYLOR, F.R.C.S. (EDIN.)
TORONTO, ONT.

FOREWORD BY W. E. GALLIE, F.R.C.S. (ENG.)
TORONTO, ONT.

FOREWORD

The principle of liquid-tight closure was first brought to my attention late in 1917 when the wards of our military hospital were filled with cases of chronic osteomyelitis and chronic septic arthritis. The simplicity and ingenuity of the apparatus devised by the Taylor brothers appealed to us so strongly that we at once gave it a trial, and I have no hesitation in stating that the method of treatment represents a distinct advance. In the osteomyelitis cases it is valuable both before and after the operation, for the purpose of cleaning out the wounds as thoroughly as possible. After operation it was often not necessary to institute any form of treatment, as the wounds healed rapidly by granulation. But in many cases the operation was followed by inflammatory phenomena in the surrounding tissues, and by profuse suppuration. In these cases the Taylor apparatus proved of the utmost value. As soon as the signs of inflammation appeared, the rubber tank was applied and the wound filled with 10 per cent. solution of sodium chlorid. Every two hours the

tank was emptied and negative pressure applied for fifteen minutes. In no instance was it necessary to keep the patient under the treatment for longer than twenty-four hours.

During 1918 and 1919 more than 200 patients were treated in this way and in all cases with satisfactory results. We have never seen such rapid improvement in suppurating wounds as occurred after the use of the Taylor apparatus.

METHOD OF TREATMENT

The tidal irrigation of wounds had its origin in France. The improved apparatus and the technic of its use were developed during the latter part of the war, in Canadian hospitals in England. Reports of cases and descriptions of the method and the appliance were published on various occasions under the caption of "liquid-tight closure."¹

The practicability of tidal irrigation is dependent on liquid-tight closure, which renders possible the copious flushing of wounds without wetting the dressings. The wound is covered by a flexible rubber cap whose brim makes contact circumferentially with the neighboring skin. This ring contact with the skin is water-tight; and the fact of its water-tightness is the sine qua non of this system of treatment. Two tubes leave the top of the cap, the inflow connected with an elevated reservoir and the outflow leading to a waste vessel set below the level of the wound. Each tube communicates with the interior of the cap which, in turn, is continuous with the cavity of the wound. From the reservoir to the waste pail, then, we have a single "pipe line," the dilated section of which is comprised by the wound and its covering cap. This cap-covered wound is capable of containing fluid, even under considerable pressure.

Flooding of the wound is effected by closing the outflow and opening the inflow tube. Suction in the wound is brought about by siphonage; this is established by closing the inflow and opening the outflow. Thus positive and negative pressure may be alternated by the manipulation of pinch cocks on these tubes. The rubber cap is seen to distend during positive pressure and to shrink during negative pressure. There is no moisture of the dressings to suggest that the wound beneath is being flooded.

Continuous irrigation is never used. The wound is filled and left filled for a time. It is then emptied and allowed to remain under the influence of negative pressure until refilled from the reservoir. The amount of tension with which the wound is filled is gaged by the height *above* it to which the fluid extends (i. e., by the water level in the reservoir), the outflow tube being closed. The force of suction with which the wound is emptied is determined by the distance *below* it to which the fluid extends (i. e., by the vertical length of the column of fluid depending in the outflow tube), the inflow being closed. So, by altering the height of the reservoir, and by raising or lowering the end of the outflow tube, complete control over each of these phases of pressure is exercised.

Positive pressure should continue until the fluid has permeated every crevice, or until the wound can hold no more. It has been customary to allow half an hour or so for the full charge of positive pressure to invade its cavity. When wounds reek with pus and teem with germs, it would be better to treat them by frequent alternations of pressure during the first few hours. The duration of negative pressure is purely a ques-

1. Taylor, W. H., and Taylor, N. B.: *Lancet* 2:452 (Sept. 22) 1917; *ibid.* 1:671 (May 11) 1918; *Canadian Army M. Corps Bull.*, April, 1918; *Canadian M. A. J.* 9:11 (Jan.) 1919.

tion of reaction, and should vary according to the intensity of the inflammatory manifestations present, lasting twenty minutes or half an hour in chronic cases, and perhaps only for a few seconds, between positive phases, in acute virulent infections. Likewise, the degree of pressure is determined by the nature of the wound. Negative pressure is more prone than positive to result in tissue reactions of undue severity. Such reactions are accompanied by pain, which is our signal to reduce the amount of suction. Frequently, however, this symptom of pain has been disregarded, and, though the reactions which ensued seemed rather severe, the condition of the wound, after the unwonted activity had subsided, was invariably such as to leave the impression that excessive reactions are salutary. Consideration for the patient's comfort is the chief indication for reducing suction. A very angry looking wound might have the treatment begun by using rapid alternations and insignificant degrees of plus and minus pressure, the duration and amount of each to be increased as the swelling subsides, as the wound becomes less sensitive, and as the effluent grows clearer.

No drainage tubes are used, for the simple reason that the wound itself constitutes, actually, the expanded portion of the conduit leading from the irrigator to the waste vessel, and that continuity of fluid pressure extends into every side track of this conduit, that is to say, into all the ramifications of the wound. Occasionally a small wire cage has been used to keep the mouth of the wound open, in cases showing a tendency to valve. The opening should be large enough to admit one or two fingers, and usually it is best to secure this by incision.

During the night, or while the patient is sleeping, neutral pressure may be substituted by allowing a moderate amount of fluid to flow in, and clipping off both tubes while the appliance is neither distended nor collapsed. This is equivalent to a continuous bath. As a fact, so much activity may be induced in the wound during the day that it is a good practice to remove the device altogether at bedtime and apply a dry dressing.

MECHANICS OF LIQUID-TIGHT CLOSURE

Certain anatomic structures exemplify liquid-tight closure—the human lips, the eyelids, the anal sphincter. The hand is capable of maintaining closure by the intelligent application of smooth-lipped vessels to the skin, e. g., the eye bath. That there is nothing inherently impossible in the idea of containing fluid on the skin is shown by the fact that the mouth of a running faucet may be closed by the palm of the hand. Nevertheless, any attempt to bandage or otherwise fasten a vessel to the surface of the body with a view to rendering it water-tight by the direct impingement of its lips on the skin is naturally foredoomed to fail. In the first place, there is not any known system of bandaging or strapping by which the contact pressure may be evenly distributed, as the human fingers are able to distribute it, and, in the second place, there is no means of varying the amount of contact pressure

as the degree of fluid pressure varies. For, even when the pressure of the contained fluid is reduced to zero, or negative pressure substituted, the same injurious amount of contact pressure must continue to impinge on the skin, and to impede the circulation of blood in the part. Previous efforts in this direction have always opposed contact, or mechanical pressure to hydrostatic pressure; whereas, with the device herein described, hydrostatic pressure is opposed by hydrostatic pressure.

The formation of a circumferential valve, operating on the surface round the wound, seemed to offer the best prospect of success in dealing with this problem. Most valves are designed to close a round aperture; but, if an area of skin should be covered by a cap, beneath which it is required to contain a quantity of fluid, the exit to be closed would not then be a round aperture; it would be the circumferential line of impingement of the edge of this cap on the skin. Accordingly, on the interior aspect of this line it was proposed to set a circumferential valve.

A general idea of the form of the device may be conveyed most conveniently by reference to a well known article of apparel to which it bears, superficially, a certain resemblance. Allusion is made to a style of headgear worn by Scotch people—the “tam-o'-shanter.” If the woolen tassel which tops it be replaced by a couple of tubes; if the headband of the “tam” and its attachment to the loose covering portion be modified slightly, as shown in Figures 1, 2 and 3, and if the whole be composed of rubber, we have, to all intents and purposes, the appliance it is required to describe.

The brim of the device, which is the circumferential valve, having been adjusted to the part so as

to circumscribe the wound, the loose top and overhanging portion of the rubber is covered and supported by a bandage. With the growth of positive pressure, the cap expands between the bandage and the skin, much as the bag of a blood pressure apparatus expands between the cuff and the limb to which it is applied. The greater the fluid pressure within the cap, the more securely the circumferential valve impinges. As the pressure of blood in the aorta closes the semilunar valves against each other, so the pressure of fluid in the cap holds the circumferential valve against the skin. Consequently, the contacting force with which the rubber bears on the surface of the part is never greater than the fluid pressure; yet it is always sufficient, for it varies as the fluid pressure varies. When not required, it is not operative; yet, if a sudden rise in pressure is produced in the cap, say by the patient turning in bed, the emergency is met. Its response is automatic.

The integrity of the closure that may be obtained merely by bandaging the device lightly to the skin, and without the aid of any adhesive substance, is hard to credit by those who have not seen it. Though a positive pressure of 40 mm. of mercury (roughly, a 20-inch column of water) answers every clinical requirement, the appliance has repeatedly withstood

Fig. 1.—Appearance of the appliance, with the inflow and outflow tubes, the loose covering portion of the rubber, and the outer aspect of the circumferential valve (A).

a test pressure of 500 mm. of mercury, and withal, it is so soft and flexible that it may be wrapped around a forearm like a compress.

RATIONALE

Perfect clearance of the wound and all its ramifications is effected by the tidal movement of the irrigating fluid. Contaminated solution is replaced periodically by fresh solution. The fluid discharged into the waste pail during siphonage is a composite mixture of the large content of the cap and the small content of the wound. The purification of the latter advances, therefore, by geometric progression, assuming that an intimate commingling of these bodies of fluid occurs with each successive cycle of the flushing process.

Two chief causes are responsible for the intermixing of the wound secretions with the fluid coming from the reservoir. First we have alternating pressures. Innumerable small recesses of the wound are "milked" of their contents by the compression incident to suction, and filled again with clearer solution during the general engorgement accompanying positive pressure. During the growth of positive pressure, the influx of uncontaminated fluid is facilitated, not only by the distention incident to positive pressure, but also by the reexpansion of the wound cavity to its normal size following the cessation of negative pressure. The second cause is fluctuation, i. e., disturbances of the hydrostatic balance existing between the rubber cap and the walls of the wound. The rubber cap is distensible and collapsible; so also, though in less degree, are the walls of the wound. During positive pressure and when the part is at rest, the common body of fluid, contained both by the cap and by the wound, is in a state of hydrostatic balance as regards their respective walls. Any force (accidental contacts, weight of the bedclothes, etc.) which impinges on the cap disturbs this balance. Similarly, this balance is upset by any muscular movement that affects the conformation of the interior of the wound. Even impulses from the heart may be transmitted. It is not unusual to see the inflow tube pulsating in unison with the femoral artery.

By virtue of these fluctuations and the ebb and flow movement of the irrigating fluid, the walls of the wound cavity are activated. Nor is it difficult to conceive rhythmic changes in posture of the tissue elements, with alternate compression and relaxation of the neighboring lymph spaces, as occurring in response to the fluid's motility. Microbes, pus cells and other débris are teased out and dislodged from their attachments, thrown into the main body of fluid, and attenuated by progressive dilution. It is the remarkable penetrating power of a body of fluid which lies on the wound, as water may be said to lie on a sand and gravel filter through which it percolates, that is responsible for such far-reaching evacuation of its most distant recesses; for the fluid which invades these recesses under the stress of positive pressure

must reappear, under the influence of negative pressure, with washings from the tissues. The tracks along which the fluid finds its way may be tortuous and narrow, may lie in the interstices formed by fragments of broken bone, or between coapted surfaces which it separates. In chronic sinuses such courses may be extremely devious and almost of capillary fineness; yet there is evidence to show that the fluid does find its way along them. No ideas that we have formed as to the penetration of wounds by solutions, when these ideas have resulted from our experience with a syringe or with multiple tubes, are at all applicable to an estimate of the extent to which fluids may be made to penetrate wounds, under hydrostatic pressure. It may be well to illustrate, diagrammatically, the principles of physics involved.

Figure 2 represents a wound covered by a liquid-tight cap, diverticula given off from the main cavity whose terminal loculi contain a little fluid, and channels leading to these loculi with their sides in apposition. The contained fluid is in a state of negative pressure. The wound walls are as completely collapsed as that particular degree of negative pressure is able to collapse them. Fluid no longer flows from the terminal loculi toward the main cavity; that is to say, the negative pressure has become static. (Strictly speaking, however, it is not quite static; for, while negative pressure is operative, the lymph which it aspirates would be flowing toward the center of the wound.) Figure 3 shows the same wound in a state of positive pressure. Here the main cavity and its diverticula contain as much fluid as that particular degree of positive pressure is capable of causing them to contain. The pressure in the terminal loculi is equal to that in the main cavity,

Fig. 2.—Sectional view of a ragged wound covered by the appliance. The rubber cover is sucked down to the skin surface and the wound is shrunk in, by the action of negative pressure.

and fluid no longer flows from the latter to the former, that is to say, the positive pressure has become static. In each instance (Figs. 2 and 3) a state of finality has been reached.

Accordingly, tidal irrigation may be defined as the slow, rhythmic transformation of the wound from the condition shown in Figure 2 to that in Figure 3 and vice versa indefinitely, or until the wound becomes sterile. That the illustrations exaggerate the distensibility of an ordinary wound cavity is neither here nor there. It must be distensible to some extent, or else its walls are rigid. Nor could this transformation have been effected by any evanescent burst of pressure. The inertia of the wound walls is not to be overcome by such momentary pressure as accompanies ordinary instillation or syringing. It required time for the main cavity to become filled; it required more time for sufficient head of pressure to accumulate within the main cavity to force the openings of the diverticula, and then a further expenditure of time for the fluid to find its way through these channels to the terminal loculi. Additional time was required for the pressure in the terminal loculi to equal that in the main cavity; all of which having had time to occur, the pressure is distributed evenly throughout, "seep-

age" of the fluid having reached the farthest recess of the wound. *It is the duration, not the amount of pressure, which is so important.*

Then, the wound having, so to speak, drunk to repletion, it is constrained to disgorge. Evacuation is inaugurated from the periphery toward the center, rapidly at first and progressively more slowly, as the limit to the collapsibility of the wound walls is reached, when static minus pressure becomes established in the wound.

There is also concrete evidence to show that the fluid actually does penetrate channels of a wound which, to all appearances, are closed. Cases were seen in which the two openings of a tunnel wound had not intercommunicated for weeks: each of these openings seemingly the outlet of a separate wound cavity. Attempts with a syringe to force fluid through from one orifice to the other, had been discontinued as futile. Such cases have served admirably to demonstrate the seepage power of fluid when activated by contrasting pressures, for, applying the cap to the larger of these openings and covering the other with gauze, if any potential channel existed between them, the fluid would seek it out and issue eventually from the smaller opening.

This would not always occur immediately. It took three days, in one particular instance, for the fluid to ooze from the mouth of a small sinus on the opposite aspect of the thigh, which was hardly suspected as having any connection with the original wound. Possibly, in this case, the communicating channel was blocked by thickened pus, and its reestablishment followed the progressive evacuation of this material occasioned by successive onslaughts of the tidal wave. It is rather more probable, however, that tumefaction of the channel was the cause of the obstruction, and that it became permeable to fluid as the reduction of this tumefaction proceeded. Reduction of swelling, as will be seen, is a constant accompaniment of this form of irrigation. In this case it was not until the thigh, which was quite large, had become reduced in size, that the small sinus began to weep. Positive pressure, of only a few minutes' duration, more often is successful in reestablishing permeability, in which case the explanation is referable solely to the laws of hydrostatics as exemplified in Figures 2 and 3. That *blind* diverticula of a ramifying wound are invaded by the irrigation fluid may be inferred from the fact that fluid was seen issuing from these seemingly occluded channels which terminated on the surface.

HYPERMIA AND LYMPHORRHEA PRODUCED BY NEGATIVE PRESSURE

Beneficent activities are inaugurated, in the tissues surrounding the wound, which transcend in importance even the thorough cleansing of its cavity. The salutary effect of increased blood supply, within certain limits, and the value of lymph as a sterilizing agent, are so

universally acknowledged as to constitute surgical maxims. A "cup" applied to the skin produces hyperemia and the same thing, on an abraded surface, causes a flow of lymph. It seems rather remarkable that so comparatively little use has been made of this knowledge in the treatment of wounds.

It is not as though the technic of applying negative pressure presented difficulties comparable with those encountered in devising means to contain fluid in a wound under positive pressure. A suitable rubber mat applied to the wound area and attached to an air exhaust would have served the purpose. Yet suction was not used. However, suction due to the rarefaction of air would need to be very powerfully exerted for a considerable period in order to draw thickened pus from a distance and, at the same time, to leave an overplus of suction to influence the flow of blood and lymph in tributary regions of the wound. Hence, negative pressure, by the abstraction of air, would be confined chiefly to the surface; also, it would interfere seriously with the proper irrigation of the wound cavity, and would be hard to regulate.

On the other hand, negative pressure transmitted through the agency of a retreating column of fluid, which is the reflux following positive pressure—this fluid being freely miscible with the wound secretions and capable of attenuating these to the consistency of water—exerts practically the same pull at the end of a long diverticulum as at the mouth of the wound. Consequently, it would not need to be more powerfully exerted at the mouth of the wound than would be required anywhere throughout its cavity. This, and the ease with which hydraulic suction can be regulated to the fraction of a degree, renders it an instrument of precision, as compared with the method of Bier.

THE EMPLOYMENT OF HEAT

The copious flushing of the wound, rendered possible by our being able to contain the fluid, secures the advantage of temperature control. Each appliance holds, according to size, from 8 to 20 ounces of fluid. This great mass of warm liquid lies over the mouth of the wound and is continuous with its cavity. Its temperature may be raised each time that a fresh supply is run in from the reservoir. This is equivalent virtually to a fomentation applied to the heart of the wound, a fomentation, moreover, that may be renewed without disturbing the dressings. To quote from Adami's monograph on inflammation, "poulticing, the employment of hot compresses, etc., are all means which have been employed for generations to 'bring an inflammation to a head'—to promote an adequate reaction."

THE FLUID USED

Antiseptics in conjunction with tidal irrigation are not contraindicated; indeed, the business of conveying the lethal dose to the haunts where microbes lurk

Fig. 3.—Sectional view of the same wound shown in Figure 2, in which the wound cavity is dilated and the appliance distended, by the action of positive pressure.

would be furthered by this mode of administering it. Nevertheless, and while admitting everything that has been said in behalf of antiseptics, it is to be pointed out that no valid reason for using them exists if germs can be "milked" from the tissues by mechanical means. Such being the case, the only question involved in the choice between an antiseptic and a simple fluid is whether the bacteria to be ejected from the wound shall be cast forth as dead or as living organisms. Any bacterial flora that can be reached by a germicide can be evacuated by the mechanical activity of a simple fluid, or destroyed by the reversal of the lymph flow and by the increased output of phagocytes which its activity induces in the wounded tissues. Furthermore, germs which no antiseptic, as ordinarily employed, can be made to reach at all are attracted to the surface by alternating pressures.

In the early days we used surgical solution of chlorinated soda (Dakin's solution). As is well known, this solution has a tendency to irritate the skin. This need not act as a deterrent if the area covered by the appliance is not extensive. By using a small sized appliance, covering little more than the mouth of the wound cavity proper, dermatitis may be prevented; and to do so is quite feasible, since the device functionates well on granulation tissue. Or, Dakin's solution may be used so long as the skin is not affected by it, and hypertonic saline solution substituted if dermatitis supervenes. These suggestions are for those who, naturally enough, may hesitate to discard a well authenticated antiseptic for a measure which they have not tried. One of the anilin dyes might be found more suitable to use with this appliance. When the wound is lined with the fibrinous products of inflammation, preliminary floodings with hydrogen peroxid are advantageous.

The fluid of our preference is a 10 per cent. solution of sodium chlorid. It is cheap; it does not waterlog the tissues; it is nonirritating to the skin, and it may be used at a properly elevated temperature. Tidal irrigation with this solution has furnished the most phenomenal results.

ANALYSIS OF THE CLINICAL RESULTS

We and others have treated more than 400 cases by this method, and the results obtained have exceeded even the expectations which the logic of the procedure seemed to justify. A good proportion of the cases treated were recently infected wounds. These had not run previously such a protracted course nor exhausted the resources of other methods, as did the chronic cases. Since, with recent wounds, the natural power to resist infection is an unknown quantity, whatever happens, even though the treatment has been the determining factor, is open to the imputation of being due to natural causes; or, at least, of not being more remarkable than might have been the case if other means had been used. For this reason we would draw attention to an analysis of the chronic cases.

The general characteristics of these indolent old wounds which, at the time tidal irrigation was begun,

had earned the reputation of being incorrigible, may be thus tabulated, in a composite way:

1. The duration of invalidism, due to wound infection, varied from three to sixteen months. The average was six months. No improvement had been noted for long periods of time, as gathered from the records and the patient's statements.

2. The condition of these wounds immediately prior to the commencement of treatment was characterized by marked induration, tenderness and swelling, for a radius of several inches around an indolent wound opening, from which much pus exuded. The swelling usually involved the whole circumference of the limb. The granulations were grayish yellow. Fracture was a complication in many instances, and the condition was often associated with aching pain. In some of the cases there was a moderate amount of fever. In one instance the temperature was 103.5 and dropped to normal in eight hours. The bacterial count was on the whole, low, averaging about ten to a field. These patients as a class were thin, of a poor color, irritable and depressed. The changes in the clinical picture which ensued after treatment was begun were truly phenomenal. It was not unusual for a wound from which there had been a persistent discharge for eight or twelve months to become sterile in less than a week, and the cavity to fill with lymph and heal in two or three weeks.

Though nearly all these patients had been operated on a number of times, in other hospitals, for the removal of foreign bodies, to promote drainage or to facilitate the insertion of tubes for instillation into various side tracks of the wound, no operative measures preceded tidal irrigation save, in a few instances, widening of the outlet. The cap was applied and the irrigation started, usually without any preparation of the wound whatever. The sequence of events was fairly constant:

(a) Within twenty-four hours, in every case, there was a noticeable reduction of induration, tenderness and swelling. The wound cavity was found to contain irrigating fluid with an admixture of pus cells.

(b) On the following day the swelling had disappeared almost entirely. The surrounding tissues, which before were brawny, were now soft and pliable, and tenderness was absent or greatly reduced. The immediate neighborhood of the wound had lost its dusky appearance. The granulations appeared red and succulent. The wound cavity contained clear irrigating fluid with an admixture of lymph, and it was no longer possible to express pus from any of its side tracks. The waste pail contained large quantities of pus. There might or might not be a sharp rise in temperature. A noteworthy phenomenon at this time was an enormous increase in the bacterial count, which had jumped from three or five per field to 100 or 200 per field.

(c) After the expiration of another twenty-four hours the swelling and induration had definitely vanished. It needs to be seen to be appreciated, this softening and dwindling of a "stove-pipe" appearing limb, almost to its normal size and texture. The wound at this time bore but slight resemblance to the wound on which treatment had been begun three days before. The bacterial count was still high. There was still a good deal of pus in the waste pail, often more than on the previous day. The temperature, if any, had dropped to normal, and the patient himself felt better than he had felt for weeks.

(d) Somewhere between the third and sixth day there was a sharp drop in the bacteriologic curve, down to one or two or none in ten fields. The excretion of pus also was reduced, the fluid in the waste pail being practically clear. Yet this fluid showed, when treated with nitric acid, a large proportion of albumin. The volume of albumin was much

Fig. 4.—Under, or "skin" surface of the appliance.

greater than may be accounted for by the osmotic power of the hypertonic sodium chlorid solution; indeed, it is not appreciably lessened in amount if physiologic sodium chlorid solution is used, showing that the exudation of lymph is due, largely, to the incidence of negative pressure.

(c) On removal of the appliance about the sixth or seventh day, the surface of the wound was clean and the surrounding tissues were everywhere pliable. After the application of gauze packs for several hours, clear, straw-colored lymph was found staining the dressings and oozing from the mouth of the wound. Frequently the wound was filled with blood. The bacterial count was usually nil in ten fields. The wound, from then on, made rapid strides toward repair.

The foregoing is a fair account of what happens with wounds of the most inveterate type. Of the events recorded, two in particular are deserving of the closest scrutiny. One of these is the greatly augmented discharge of pus cells during the initial stages of the irrigation. Better drainage of the wound does not satisfactorily explain this increment, since the wound proper is capable of holding only a few drams of pus, and this small quantity is washed away during the first few hours of the irrigation. Moreover, the quantity discharged is out of all proportion to the amount, either that the wound can hold, or that its lining granulations would normally excrete within the time. It is believed that the increment is due, both to the increased exudation of leukocytes from the tissue spaces and to their accelerated transmigration from the capillary vessels, in response to the hyperemia produced by negative pressure.

Analogous to this forced excretion of pus, and even more significant, is the abrupt rise and subsequent drop to zero of the bacteriologic curve. Is the rise due only to increased excretion, or is it evidence of stimulated microbial growth? The concomitant amelioration of the clinical signs, and the reduction of swelling, proceeding hand in hand with the copious discharge of inflammatory products, point unmistakably to the conclusion that it is a "catharsis" which occurs, of lymph, pus cells and bacteria, from infected tissues. This view is supported also by the fact that the elevation of the bacterial count was always higher, and the increment of pus cells always greater, in old-standing cases with widespread induration and swelling. Recent wounds frequently showed little or no increase.

The thoroughness with which the neighboring tissues of a wound are "washed" is indicated by the aseptic manner in which Thiersch's skin grafts "take" on a foul granulating surface which first has been cleansed, for two or three days, by tidal irrigation, in which the negative phase has been emphasized to the point of securing a definite reaction. If a portion of such an area is thus treated, and the remaining portion is treated in the customary way, any antiseptic whatsoever being used, and if Thiersch's grafts are then applied to each portion, a marked difference will be observed in the behavior of these two sets of grafts. This test is commended to any one in doubt as to the relative merits of the two procedures.

CONCLUSION

To what extent may we attribute to a plan of treating wounds the clinical results which follow its employment? Experiments verified by "controls" are unequivocally conclusive; yet, for reasons that are obvious, it is rarely possible to apply this method of verification to the treatment of wounds. "Post hoc propter hoc" is notoriously fallacious, since most wounds tend naturally to heal. Nevertheless, if the previous history of a wound infection has been long and tedious, the clinical manifestations of disease overt and palpable, and the condition most intractable; then, if the subsequent history is inaugurated *abruptly*, the clinical signs ameliorate rapidly and the wound, thereafter, makes for repair, and if this right-about-face transformation coincides invariably, in point of time, with the institution of a certain treatment, surely it may be said that the state of the wound prior to the treatment serves well enough for a control to the effect which follows it. In the judgment of those of our surgical staff who had occasion to watch these cases from day to day, the results herein described were extraordinary, and were considered as the outcome of the tidal movement imparted to the irrigating fluid.

Rather would it have seemed strange had the power to control the pressure of the irrigating fluid *not* modified, to some extent, the course of wound infections, considering what a physiologic factor this one of pressure is. In respect to any therapeutic measure capable, as this is, of altering profoundly the physical conditions under which the tissues live, it would not have lacked significance had 400 wounds been treated, with uniformly good results. The tissues were activated to a degree which might have given (and as a fact

Fig. 5.—Appliance being bandaged to a wounded thigh.

did give) rise to apprehension. It seemed as though such interference must have some effect, and there were reasons to foresee that the outcome would be gratifying; for though the procedure in question is radical in the sense that its component elements had not been employed in combination before, it is the reverse of radical in that each item of its rationale is the expression of a surgical maxim. Thorough evacuation, drainage, scrupulous cleansing of the wound cavity and its lining granulations, hyperemia, lymphorrhea, warmth, etc., are all old friends whose familiar features need not seem the less familiar for being associated together.

It is not possible, in the scope of the present paper, to give minute instructions for the management of every contingency to be encountered in the different types of cases, nor is it altogether necessary. Wounds may be irrigated in this tidal manner with less of troublesome detail than any other method of wound treatment demands. This is true of any wound situated on an accessible surface of the body which may be conveniently covered by the appliance. Yet, owing to inattention to the laws of physics, or to the surgeon's undue apprehension in the use of an unfamiliar method, and sometimes through the indifference of

a nurse or the whim of a nervous patient, we have seen the treatment hurriedly discontinued, the surgeon nothing doubting that he had given it a trial. Were tidal irrigation as difficult as, actually, it is easy to accomplish, it would still repay the effort made to understand it, and the use of one's constructive faculty now stands, the basic fact is established, of a simple to improve it and to simplify its technic. As the mat- and convenient means of containing fluid in a wound. An appreciation of what this fact implies, and the exercise of no more thought and enterprise than most surgical maneuvers impose on the surgeon, will be rewarded by results such as cannot be obtained in any other way.

SUMMARY

1. The irrigating cap herein described is designed to make liquid-tight contact with the skin, circumferentially about a wound, without the aid of any adhesive substance whatever. The mechanical expedient employed, to this end, is used here for the first time in surgery.

2. The cap permits fluid to be contained in a wound without leakage, even under considerable pressure, and without constriction of the part or obstruction to its blood supply.

3. From this a system of wound treatment has resulted whose rationale conforms to the established principles of surgery.

4. This treatment comprises the repeated filling and emptying of the wound and the alternate use of positive and negative pressure, the duration of each of these phases of pressure being sufficiently prolonged to insure its maximum effect on the tissues.

5. The ebb and flow movement of the fluid is shown to have a marked cleansing action as regards the wound secretions, the effect of negative pressure being to induce hyperemia and lymphorrhea, to increase phagocytosis, and to cause a forced output of bacteria from the wound.

Ill Health and Ignorance.—Much of the ill health in the homes of people is due to ignorance. From that ignorance often emerge the beginnings of disease. It is at such times that the first fatal step is taken, and a symptom regarded as trivial, too trivial, indeed, to require medical aid, is dealt with by a much advertised "cure all" patent medicine obtained from a chemist. Deceived by a blatant advertisement, which preys on ignorance, the home treatment is pursued until it is proved worthless during which valuable time is lost, followed by the development of more manifest disease symptoms.—*Medical Press and Circular* 109:66 (Jan. 28) 1920.

CHRONIC LEUKORRHEA: ITS PATHOLOGY AND TREATMENT*

ARTHUR H. CURTIS, M.D.

CHICAGO

Efforts to advance our knowledge of chronic leukorrhea have thus far yielded only moderate success. The underlying pathology is not thoroughly understood, and treatment has been distinctly unsatisfactory. For these reasons I have made a prolonged study of the subject in an endeavor to learn more about the problems involved.

ETIOLOGY OF CHRONIC LEUKORRHEA

The gonococcus is the primary cause of most chronic purulent discharges of women who have not borne children. This organism cannot often be isolated from chronic cases, but none the less it causes the original discharge, decreases the resistance of the tis-

sues, and thus prepares the soil for mildly virulent bacteria which thereafter stubbornly resist our efforts to dislodge them.

In women who have borne children, resistance is decreased through lacerations, relaxation of supports, continued passive congestion and erosions. Here again, bacteria of low virulence find a foothold and produce chronic discharges which are cured with the utmost difficulty.

An especially important type of chronic leukorrhea, and one which is very difficult to cure, is that associated with pelvic cellulitis. Whether the cellulitis persists because of a focus lodged deep in the cervical glands, or the cervix becomes reinfected from the cellular tissues, remains in my mind a somewhat open question.

In any event, the discharge tends to recur even after apparent recovery.

Less important and less frequent cases, neither the result of gonococcal infection nor consequent to pregnancy, are "nonspecific" venereal infections and persistent mild infections due to abnormally low resistance.

Bacteria.—The bacterial flora of chronic cases is fairly uniform.¹ Anaerobes, especially gram-negative bacilli, are most numerous. At least four types of gram-negative diplococci are encountered. Most

Fig. 6.—Apparatus applied, the inflow tube connected with an irrigating can held by a stand beside the bed, and the outflow tube joined to a length of rubber tubing leading to a waste pail below. The appliance is completely covered by the bandage. The patient is able to conduct the irrigation himself. By opening the pinch cock on the inflow tube and closing the one on the outflow, the wound is filled. By reversing the procedure the fluid is siphoned off and negative pressure maintained by the weight of the column of fluid which hangs in the outflow tube.

important of all are gram-positive diplococci; these may be anaerobic or aerobic, and are almost always found in those cases which are subject to recurrent symptoms of acute inflammation.

PATHOLOGY OF CHRONIC LEUKORRHEA

Pathology of the Cervix.—Some years ago, I became convinced that hypertrophic infected cervical glands are a most important factor in chronic leukorrhea. Study of curetted material from the present series of cases confirms this view. Distinct evidence of chronic cervical infection was obtained from twenty-one out of twenty-two patients with chronic leukorrhea (Fig. 1). Gland hypertrophy was the rule; small areas of scar formation were frequent; in addition to plasma cells and other round cells, the microscope usually revealed abundant polymorphonuclear leukocytes.

Only within the last fifteen months has the frequency of two other cervical lesions been recognized: endocervical granulations and strictures. Their significance is perhaps comparable with granulations and strictures of the male urethra.

Granulations are felt to grate on the dilator as it is passed into the cervix. They may be found anywhere along the canal.

Strictures are most often encountered midway between the external and internal os or at a higher level. Some dilate with ease; others are firmly resistant. Differentiation of strictures from normal arbor vitae occasionally causes difficulty.

The Relation of the Endometrium to Chronic Leukorrhea.

—In a previous bacteriologic and histologic study² of the endometrium from 118 uteri removed to remedy various pathologic conditions, I found that chronic infection of the uterus above the level of the cervix is infrequent. Patients whose endometria yielded bacteria almost all had salpingitis with equally good growth. It was concluded that chronic endometritis, independent of infection of adjacent pelvic tissues, almost never occurs as a clinical entity.

The present study of chronic leukorrhea indicates that endometritis may occasionally accompany chronic cervicitis (Fig. 2). For the purpose of comparative histologic study, scrapings were obtained from the fundus at the time of diagnostic curettage of the cervix. As previously mentioned, chronic cervicitis, often of considerable severity, was present in all except one of twenty-two curetted patients. Six revealed evidence of chronic endometritis, but in no instance was the inflammation severe.

It is scarcely necessary to mention that the vaginal portion of the cervix also contributes to leukorrhea when glandular erosions develop on it. Occasionally erosions become implanted throughout the vagina, in which case the vaginal walls produce a discharge.

Skene's ducts, the urethra, and Bartholin's ducts and glands are often considerable factors in the persistence of leukorrhea. This is notably true of infection of Skene's ducts.

TREATMENT

Only chronic leukorrhea is under consideration. Most acute discharges tend to improve spontaneously. Remedies too numerous to discuss have been extensively used. These include curettage, treatment of the uterine cavity, applications to the lower cervix, vaginal douches, administration of glycerin or other hygroscopic solutions, vaginal tampons, various kinds of powders, and vaccines. We have tried them all, with very indifferent results.

According to my interpretation, most popular procedures are not sufficiently directed toward the pathology of leukorrhea. Deep cauterization of the cervix, as employed by Hunner,³ is theoretically of value, and is said to be helpful in selected cases.

In the series herewith reported, the patients have been subjected to a thorough pelvic examination, the reaction of the discharge tested, smears obtained from the cervix and vagina, and a set of cultures made.

Gross pathologic lesions are corrected surgically.

The usual hygienic measures are instituted.

Treatment of the Cervix.—The most usual and most difficult focus to eradicate lies in the endocervix. Unless the

discharge is essentially of vulvovaginal origin, radium is advocated in all severe cases of persistent chronic leukorrhea. After thorough dilatation, the cervix and fundus may be curetted for diagnostic purposes.

Fifty mg. of radium, preferably two 25 mg. tubes in tandem, are introduced high into the cervix, held by a suture passed through the external os, and left for several hours. One or more subsequent radium treatments of shorter duration may be required. It is thought best to plan on an interval of from ten to twelve weeks' duration between applications.

Each radium tube employed in the treatment of this series of cases has been screened by a double gold capsule with a total thickness of 2 mm. The capsule in turn has been incased in dental rubber. At present the screen has been reduced to a single rubber covered

Fig. 1.—Chronic cervical infection; typical severe endocervicitis in a case with leukorrhea of two years' standing; $\times 450$.

gold capsule of 1 mm. The duration of application has been correspondingly decreased.

Examination of cervical tissues after successful radium treatment (Fig. 3) reveals atrophy of the glands, a relative increase in fibrous tissue, and the disappearance of any microscopic evidences of infection.

Skene's ducts harbor the next most important focus. At the time of radium application, or under procain anesthesia, the blunt end of a needle, held in forceps, is threaded into the duct lumen, and its end is forced through the base of the duct so that the needle head protrudes into the vagina. The duct is split with a knife and the tract fulgurated.

Bartholin duct infection may be eradicated by similar treatment. Infected Bartholin glands rarely require excision.

The urethra is occasionally treated by dilatation, aided by instillations of weak silver nitrate solution.

STUDY OF MATERIAL

In 1914, there was reported an intensive bacteriologic study of eighty-five cases of chronic leukorrhea. At the same time the results of various kinds of treatment were carefully observed. Before the present study was begun, many additional patients had been treated. The therapeutic results obtained in that entire series were distinctly disappointing.

Treatment of the forty-six patients now under consideration has been essentially that described above. All were afflicted with long-standing persistent discharge, in most instances sufficient to necessitate the constant use of napkins to prevent soiling of linen. A summarized study of these cases is presented in the accompanying table.

GROUP 1.—*Recovered* (twenty-five cases).—Seventeen of these patients had free discharge; in eight it was excessive. All have now returned to a normal condition.

A history of gonorrheal etiology or definite evidence of previous gonorrhea was present in fifteen. In three the leukorrhea followed pregnancy. Radium treatment for uterine hemorrhage had produced stricture and profuse

Fig. 2.—Endometritis, a complication of cervical infection; plasma cells abundant; numerous polymorphonuclear neutrophils present; × 300.

leukorrhea in one instance. A highly irritating chronic discharge was due, in one patient, to repeated douches with cold tap water.

Of five patients with leukorrhea of uncertain etiology, two had been uncomfortable for years because of profuse, creamy discharge. One of these suffered from chronic pelvic cellulitis and femoral thrombophlebitis; the other had cellulitis without evident tubal involvement.

Fifteen of this group of patients had cervical erosions, two of which were slight; seven of moderate size, and six large. Two were excised; all the others disappeared under treatment.

Cervical granulations or strictures were encountered nine times. Obstruction from strictures was of high grade in six cases.

Radium treatment was given to twenty of this group; twelve received one treatment; six, two treatments; one, three treatments, and one, four treatments. I wish particularly to mention one patient whom we had treated for ten years without relief. Fulguration of Skene's ducts and one short radium treatment resulted in an absolute cure within six weeks.

Artificial menopause occurred in one of this group. This patient, 39 years of age, with scanty menstruation, developed amenorrhea after a treatment of 500 millicuries.

GROUP 2.—*Improved* (seven cases).—One patient with excessive foul discharge developed leukorrhea during pregnancy. Abortion followed, with persistence of discharge thereafter; this continued throughout a succeeding pregnancy, which terminated at seven months. Repair of a cystocele, removal of an everted eroded anterior cervical lip, and two short treatments with radium have resulted in almost complete recovery.

A patient 33 years of age had been subjected to salpingectomy and removal of one ovary two years previously; the second ovary, although slightly involved, was not removed. Destruction of infected Skene's ducts and dilatation of a granular, strictured cervix, with one application of radium has decreased a profuse purulent discharge almost to normal. An undesired menopause was ushered in. This patient presumably had very little normal ovarian tissue at the time radium was given.

Another patient with badly infected Skene's ducts, whose scrapings revealed severe endocervicitis and normal endometrium, had received no benefit at our hands from two years' treatment of various kinds. Five months ago Skene's ducts

were destroyed, and the cervix was dilated and treated with radium. Extreme malaise disappeared; leukorrhea has dwindled to a slight amount.

The fourth and fifth cases, with chronic cervicitis and infected Skene's ducts, showed marked improvement after duct destruction and one radium treatment. Both have very recently received a second treatment, the results of which are not yet evident.

Finally, the very slow response to treatment, encountered in two patients, deserves brief comment.

A woman, aged 23, with offensive, foul, extremely profuse leukorrhea of three years' duration, was found to have all the usual foci of infection, including cervical granulations and complete cervical obstruction. An enormous erosion, bathed in pus, covered nearly the entire vaginal portion of the cervix. Eight months ago Skene's ducts were destroyed, the stenosed cervix dilated, and 600 millicuries of radium administered; there was no improvement. Two months later, a second radium application was made; again there was no notable improvement. Menstruation remained uninfluenced. Three and one-half months ago, after explanation that more radium might suppress menstruation, she received a third treatment. There was no evident improvement for many weeks, but the erosion has now entirely healed, and the malodorous, fetid discharge has given way to a much less abundant creamy leukorrhea; although still profuse, it is not offensive. Menstruation was excessive and prolonged after the last radiation, but has now returned to normal. It is planned to give a final treatment within a few weeks, after a rest of four months since the last application.

The other patient with slow response to treatment had a profuse leukorrhea of two years' duration. It was only after a third administration of radium that the discharge was influenced. At present, recovery is almost complete, but moderate increase in the menstrual flow warns that we have reached this patient's present tolerance for radium. If more is given, it will be a short exposure after many months' delay and with full understanding that temporary amenorrhea may result.

GROUP 3.—Treatment Interrupted or Recently Begun (ten cases).—Two patients disappeared after a single treatment and have not been heard from. Eight cases are too recent to permit deductions concerning the efficacy of treatment. These cases are included in the present series chiefly because material obtained from them has been used in that portion of this report which is concerned with the pathology of chronic leukorrhea.

GROUP 4.—Not Improved (four cases).—A patient with moderate leukorrhea had suffered for many years with left-sided pelvic cellulitis, which was the result of infection after abortion. Infection of Skene's ducts, both Bartholin ducts, and one Bartholin gland, was also present. There was a slight erosion of the cervix, but no strictures or granulations. Scrapings revealed considerable inflammation, which was equally pronounced in the endocervix and in the endometrium. The infected ducts were destroyed, and the cervix was treated with radium. There has been no improvement

in the condition; this is ascribed to inaccessible deep-seated pelvic infection.*

A patient with irregularly recurrent pain in the right pelvis (cellulitis), since infection at childbirth fourteen years previously, suffered greatly from vulvitis caused by a moderate, thin, milky discharge. At operation elsewhere a catarrhal appendix and normal tubes and ovaries had been found. Two radium treatments have totally failed to give relief.

The third patient in whom treatment has been unsatisfactory had, in addition to the discharge, an otherwise symptomless relaxation of uterine supports with moderate displacement backward and to the right. She has received three radium applications at intervals of several months. Nervousness, flushes and slightly irregular, increased menstruation followed the last treatment. Slow improvement is manifest, but recovery is improbable unless radium is employed in an amount sufficient to destroy ovarian function.

In the last of this group there was low-grade infection, which apparently invaded all of the pelvic organs and cellular tissues. A mild arthritis involved many joints and caused much distress. Slight improvement has been obtained through occasional dilatation of the strictured cervix. It is thought that radium treatment is not well adapted to this type of case, and will be dispensed with if possible.

COMMENT

Of thirty-six patients available for thorough treatment, thirty received radium and twenty were subjected to destruction of Skene's ducts. Twenty-five recovered, seven were distinctly improved, the result in one was doubtful, and three were not materially benefited.

Menopause was produced in two patients. One of these, 39 years of age, with scanty menstruation at the time of radium treatment, received 500 millicuries. The other patient, with one remaining partly diseased ovary, received 700 millicuries.

Sufficient radium distinctly to influence ovarian activity was given to three patients, each of whom received three treatments at infrequent intervals. Symptoms of impending amenorrhea in these three patients were characterized by greatly increased irregular menstruation, with associated nervousness and tendency to occasional flushes. All returned to symptomatically normal condition within three months.

In explanation, it should be stated that these patients were aware of the possibility of artificial menopause before their last radium treatment, but decided to incur the necessary risk.

Granted that radium is a remedy of value, certain questions arise. How many patients, in the course of radium treatment directed to the relief of chronic leukorrhea, will require radiation in an amount suffi-

Fig. 3.—Healed cervix, six months after radium treatment for chronic leukorrhea; great decrease in number of glands; those that persist are atrophic; $\times 120$.

4. A recent message from this patient states that the discharge has entirely ceased. This report has not been confirmed by local examination.

cient to produce amenorrhea? Again, in those cases amenable to cure through moderate doses of radium, are the functions of childbearing or formation of internal secretion materially disturbed, even though menstruation continues?

Experience thus far indicates that the pathologic changes in most cases are within reach of radium. The present plan is to discontinue the use of a double gold screen, replacing it with a single rubber covered gold capsule, not over 1 mm. in thickness. Short applications, made at intervals of not less than ten weeks, permit observation of the effects of each treatment. Even in repeatedly treated stubborn cases it is thus possible to avoid production of premature menopause. Whether it will often be necessary to discontinue treatment before cure is effected remains to be determined.

It is my opinion that radium in amounts small enough not to disturb menstruation is not to be feared as a cause of sterility. On the other hand, it will probably not be especially beneficial in the relief of sterility because a large percentage of patients with cervix infection have already suffered from catarrhal salpingitis. Two exceptions have been encountered: A patient of Dr. Watkins, who had not been pregnant for five years, complained of sterility. Conception developed within three months after relief of a cervical catarrh through an application of 500 millicuries of radium. The other patient received 925 millicuries. She is now pregnant and expects to be confined in two months.

Finally, a word on the relationship of chronic leukorrhea to focal infections. Chronic arthritis has been noted with unexpected frequency in patients without other demonstrable foci; the regions most involved are the lower spine, sacro-iliac joints, and the finger joints. It is too early to determine the amount of improvement obtainable through cure of the vaginal discharge; this evidence will be awaited with interest.

CONCLUSIONS

1. Important foci of infection are to be found in Skene's ducts and the uterine cervix. The chief cervical lesions consist in hyperplasia of infected cervical glands, endocervical granulations and strictures, and erosions of the cervix.

2. Discharges arising from Skene's ducts are relieved by free incision and fulguration of the infected tracts.

3. Chronic leukorrhea of cervical origin is, in most instances, amenable to cure through dilatation of strictures and treatment with small doses of radium applied at infrequent intervals. The prognosis is less favorable in those cases with chronic cellulitis or uncorrected gross pelvic lesions.

104 South Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. FRANCIS REDER, St. Louis: The genital tract of woman in a normal condition is usually bathed in a leukorrheal discharge. There has been a tendency to disregard the true meaning of the word leukorrhea, the term being applied to almost any discharge escaping from the female genital fissure. When could a leukorrhea be considered chronic or pathologic? Usually when the woman consults the physician. It is to be regretted that women frequently disregard a vaginal discharge for a long time before seeking advice. This often has its bad consequences, inasmuch as a discharge where bacterial invasion has been of short duration is more readily

relieved than a discharge of long standing, where infectious micro-organisms have been allowed full freedom to accomplish their contamination, thus increasing the difficulties of a cure. Furthermore, the anatomic peculiarity of the structures forming the canal of the cervix and the cavity of the uterus favor the persistency of the discharge. There is no submucosa. The mucosa is intimately connected with the underlying muscularis, the extremities of the glands dipping more or less freely into that structure. These occluded and buried glands harbor the micro-organisms. The gonococcus is responsible for a chronic leukorrhea in the majority of cases. A good history will greatly assist in arriving at the true nature of the discharge. It is well to bear in mind that in the adult a gonococcus infection invades the vulva, especially the urethra and vulvovaginal glands, and the cervix uteri. Rarely does the vagina suffer. An infection of the cervix uteri is often primary. In instituting treatment for a chronic vaginal discharge, it should be ascertained if it is a vulvar, a vaginal, a cervical, or an intra-uterine leukorrhea. Often a discharge having its origin in a chronically inflamed cervix, one which has become indurated by alveolar hyperplasia, will be readily cured by a plastic operation. As far as radium is concerned: I have not used it. The present status of the use of radium in chronic leukorrhea, as I see it, is this: Will a woman in the menstrual age consent to have her chronic leukorrhea cured at the risk of sacrificing her menstrual function?

DR. THOMAS J. WATKINS, Chicago: Dr. Curtis' work follows up the work of Hitchman and Adler which demonstrated that the amount of endometrium obtained on curettage depends on the menstrual cycle and has very little relation to the question of infection. The bacteriologic work done, especially by Dr. Curtis, three or four years ago, showed that in the great majority of cases the cavity of the uterus is sterile; that the bacterial invasion is limited to the cervix. This means that curettage is an operation which has been done much too often, that there is almost no indication for curettage of the endometrium, except for diagnostic purposes. The reason why curettage has helped in some cases of uterine leukorrhea is that the cervix was dilated. Dilatation of the cervix is valuable to improve drainage. The question of the care of infections in the vaginal orifice is a very important one, one very frequently neglected. As to the action of radium in these cases, I wish to emphasize the fact that erosion of the cervix will almost invariably heal over after the use of radium. It is important to regulate the dose so as not permanently to injure the function of the ovary. Radium diminishes the number of epithelial cells and increases the number of connective tissue cells and in this way drains the deep glands in the cervix.

DR. PETER B. SALATICH, New Orleans: If the uterus is displaced backward, you can plicate and cut as much as you like and the patient will continue to have leukorrhea because the congestion is permanent and continuous. A young woman came to me with her face full of acne. She had headache and joint troubles. I examined her cervix and found it entirely devoid of mucous membrane. I used phenol and curetted. The patient was not relieved. Then I used a solution yielding active chlorin, and in five or ten applications the patient was well.

DR. ARTHUR H. CURTIS, Chicago: Except in a few instances, when granulations were very excessive, a preliminary curettage was done only for diagnostic purposes. It is not advisable to apply radium when there is marked infection of the upper genital organs. One of the men from the Pasteur Institute who visited with us in Chicago some months ago, stated that he had used radium in 250 cases of pus tubes and that the results were very encouraging. To say that the use of radium is out of proportion to the seriousness of leukorrhea or the infections which cause leukorrhea, indicate that the speaker is a man, not a woman. If he had to walk around with a profuse purulent discharge and was forced to wear a napkin all of the time, he would be glad to have radium used. I do not believe in giving enough radium to sterilize the patient or interfere with the menstrual function. In most of the cases of this series I used a thick double gold

screen. Recently I have screened much less and now I usually employ a gold capsule half a millimeter in thickness, surrounded by a thin covering of dental rubber. I have tried innumerable remedies for the cure of leukorrhea, but have found none of them efficacious.

RESULTS OF THE EXPOSURE OF ANIMAL OVARIES TO THE RAYS OF RADIUM*

JOHN M. MAURY, M.D.

MEMPHIS, TENN.

The experiments here recorded were made for the purpose of determining the changes brought about in the ovaries of rabbits by exposing them to 50 mg. of the element radium for twelve hours. This dosage was selected because it is that generally used in cases of so-called idiopathic uterine bleedings but which are now regarded as being due to an abnormal condition of ovarian secretion.

As some of these cases, particularly in young subjects, can be cured by the internal administration of pituitary extract, it is possible that not all of them are due entirely to ovarian conditions, some being due rather to a disturbance of the balance normally existing between the output of the pituitary gland and the ovaries.

It is well known that the intra-uterine application of radium has an effect on menstruation proportionate to the dose, 50 mg. of the element applied for twelve hours being sufficient to stop menstruation for several months, and in some instances to establish the menopause permanently. The generally accepted theory is that this result is brought about by a destructive action of radium on the follicles most advanced in development, menstruation returning after the young follicles, on which radium is supposed to have had no effect, have had time to mature. Little account, so far as I can learn, seems to have been taken of the effect which must be produced on the endometrium, on which its greatest power must be exerted.

Considering the small amount of radium used in these cases and the distance from the uterine cavity to the ovaries, to one who is accustomed to the use of radium there must be some doubt arising as to the results being brought about in the manner claimed. It is also difficult to imagine a satisfactory reason why the mature follicles should be killed and the less mature ones remain uninfluenced, especially as every-

where else in biology the less mature a thing is the greater its susceptibility to disintegrating influences. As a matter of fact, I have not been able to substantiate this theory by microscopic examination of the ovaries treated, and I have other evidence which seems to show that neither the large nor the smaller follicles are influenced by this dosage of radium.

In determining changes which may have resulted from treatment, great difficulty is encountered because the normal ovary presents no fixed standard for comparison. In normal ovaries, degeneration is present to a greater or less degree in follicles in all stages of development, comparatively few completing the cycle of growth to maturity and rupture with the discharge of a living ovum. This is particularly true in the rabbit, because ovulation does not take place without copulation. Follicles maturing except at this time do not continue to live, but die and degenerate and, as pointed out by Graves, all those follicles arriving at maturity during pregnancy must become atretic. It was therefore necessary to examine a large number of

normal ovaries to familiarize oneself with the great variations that may exist.

Ovaries of rabbits differ from the human ovaries in the amount of epithelial tissue present. While the human ovary may be described as a connective tissue organ containing graafian follicles and having a fibrous capsule outside of which is the germinal epithelium, the rabbit ovary is a mass of epithelial cells having a thin connective tissue cortex surrounded by the capsule and germinal epithelium. Most of the follicles are found embedded in the con-

Fig. 1.—Blood vessels nine weeks after 600 mg. hours of radium. No endarteritis; peculiar thin walled vessels filled with blood.

nective tissue cortex. The epithelium of the body of the ovary can easily be distinguished from the epithelium of the corpus luteum by the latter cells being of larger size and surrounded by the theca.

The ovaries of rabbits occupy a rather fixed position in either flank, close to the abdominal wall and just above the crest of the ilium. In this position they are much closer to radium placed on the skin surface than are the ovaries of the human being to radium placed in the uterine cavity. Having less tissue intervening, they are therefore more susceptible to the action of the rays.

Fifteen female rabbits were treated, each being given a dosage of 600 milligram hours, the radium applied to the skin surface overlying the ovaries. One was killed in three weeks, two in four weeks, two in five weeks, four in six weeks, three in eight weeks and four in nine weeks. The ovaries removed were not touched with fingers or forceps. They were placed in 70 per cent. alcohol at once and run up for paraffin sections as soon as possible. The first few were sectioned serially and examined throughout. This con-

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

sumed much more time than was available, and was found to be unnecessary. Therefore in the others, from fifty to seventy-five sections were removed from each side and from the middle portion of the ovary and examined, making about 150 to 200 sections from each ovary. In the examinations of sections, special

a state of degeneration. Deducting, therefore, the seven ovaries not containing follicles of sufficient size to be supposedly affected by radium, there remain twenty-three, twelve of which contained large follicles showing no effect from treatment.

In addition to this evidence, two rabbits were put with a male and became impregnated five weeks after treatment, in one four and in the other five embryos being removed from the uterus several weeks later—rather convincing evidence of the viability of the ovum when it was discharged from the ovary.

Two other animals which had become pregnant were later treated and did not miscarry, indicating that the membrana granulosa of the mature follicles, from which the corpus luteum cells are probably formed, was not degenerated; for it is well known that if the corpus luteum of pregnancy is destroyed in its early stages, the fetus will be cast off.

From these results I think it a fair deduction that a 600 mg. hour dosage of radium does not produce degeneration of the follicles of the ovaries.

REPORT OF EXPERIMENTS

RABBIT 1.—Killed in three weeks after 600 mg. hours of radium.

Right Ovary: Quite small. Not more than half the thickness of the left ovary.

1. The germinal epithelium is normal.
2. This ovary resembles the human ovary in that the connective tissue exists throughout and there is no epithelium except in a few corpora lutea. A cirrhotic ovary.
3. Very few primordial follicles and only a few small

Fig. 2.—An atretic follicle, to illustrate the difference between degenerating follicles and nondegenerating ones.

attention was given to the germinal epithelium, the connective tissue cortex, the blood vessels and the follicles.

Macroscopically, the ovaries varied greatly in size. One, a sclerotic ovary, was a mere strip of tissue composed, as seen under the microscope, of only connective tissue with almost no follicles. I do not think this was the result of the treatment because the ovary was removed only three weeks after treatment, and there were no signs of follicles in a state of degeneration and almost no small follicles of any size, a change so great that it could hardly have taken place in three weeks. The variation in size seemed to depend on the number and size of the atretic follicles and corpora lutea present. Both in number and size these structures varied greatly in different ovaries. In all ovaries examined, the germinal epithelium was present and in normal condition. The connective tissue cortex varied much in thickness in different ovaries, even the two ovaries from the same animal presenting considerable variation. The blood vessels showed no signs of endarteritis, and as they normally have unusually thick walls, this change could easily have been observed had it been present.

As would naturally be expected, the greatest variation was shown in the condition of the follicles. In seven of the ovaries examined there were no follicles approaching maturity either alive or in a state of degeneration. In twelve there were living follicles at or close to maturity which showed no evidence of having been affected by the treatment. In the remaining eleven all the large follicles were in

Fig. 3.—A nearly mature nondegenerating follicle eight weeks after 600 mg. hours of radium; shrinkage of granulosa from theca is postmortem.

follicles; some alive, some dead and degenerating. No medium sized follicles and no large ones. None in a state of cystic degeneration.

4. Blood vessels normal, but few in number.

Left Ovary: Double the size of right one.

1. Germinal epithelium normal.

2. Connective tissue cortex surrounding epithelial mass.

3. Two primordial follicles which seem to be normal. Fairly large number of small follicles, some degenerating and some in normal state of preservation. A considerable number of large atretic follicles. All large ones atretic.

4. Blood vessels normal.

RABBIT 2.—Killed four weeks after 600 mg. hours of radium.

Fig. 4.—A nearly mature nondegenerating follicle nine weeks after 600 mg. hours of radium; also shows smaller follicle in state of preservation.

Right Ovary: 1. Germinal epithelium heaped up over one portion of the ovary, opposite which, in the cortex, are a very large number of primordial follicles. This heaping up of the germinal epithelium is irregular in outline and not even, as when cut on a slant.

2. The connective is greatly in excess of the epithelial body of the ovary, extending in places deep down into it.

3. Primordial follicles are in large numbers. A considerable number of small follicles beyond the primordial stage. A number of large follicles just under maturity not in a state of degeneration. A few atretic follicles.

4. Blood vessels normal.

Left Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex normal.

3. Moderate number of primordial follicles. Very few small follicles. No follicles of any size not in a state of cystic degeneration.

4. Blood vessels normal.

RABBIT 3.—Killed four weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.

2. Connective tissue normal.

3. Primordial small and medium size follicles normal. One large nearly mature follicle undegenerated. A few large atretic follicles.

4. Blood vessels normal.

Left Ovary: 1. Germinal epithelium normal.

2. Connective tissue normal.

3. Many primordial and small follicles. No follicles of size supposedly to be affected by radium.

4. Blood vessels normal.

RABBIT 4.—Killed five weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex normal.

3. Primordial follicles relatively few. A fair number of small follicles, some of which are degenerating. No large follicles and no atretic follicles.

4. Blood vessels normal.

Left Ovary: Shows the same condition as the right ovary.

Neither shows follicles of a size to be supposedly influenced by radium.

RABBIT 5.—Killed six weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex rather thin.

3. Primordial follicles relatively few, and many of them in a state of degeneration. Some small follicles, but none of medium or large size. No atretic follicles. The ovary is of fair size, but contains only a small amount of follicular tissue.

4. Blood vessels normal.

Left Ovary: 1. Heaping up of germinal epithelium in places. Normal elsewhere.

2. Connective tissue thin in places, but quite thick in others where numbers of primordial follicles are embedded.

3. Primordial follicles are found in numbers in places. Scarce in other places. Small and medium size follicles few. A few large cystic follicles. One large nearly mature undegenerated follicle.

4. Blood vessels normal.

RABBIT 6.—Killed six weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex thin.

3. Few primordial follicles. A large number of small follicles not degenerated. A number of nearly mature undegenerated follicles. A few atretic follicles.

4. Blood vessels normal.

Left Ovary: Quite small in size.

1. Germinal epithelium normal.

2. Connective tissue cortex normal.

3. Few primordial follicles. Some small follicles not degenerated. Some large degenerated follicles, and several almost mature not degenerated.

4. Blood vessels normal.

RABBIT 7.—Killed six weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex normal.

3. A few primordial follicles. A number of small follicles,

Fig. 5.—A nearly mature nondegenerating follicle six weeks after 600 mg. hours of radium.

some degenerated, others not. No follicles near maturity not degenerated. Several large atretic follicles.

4. Blood vessels normal.

Left Ovary: A number of primordial and small follicles in normal state. No follicles nearing maturity not in state of degeneration. Other structures, i. e., germinal epithelium, connective tissue cortex and blood vessels, in normal state.

RABBIT 8.—Killed six weeks after 600 mg. hours of radium.
Right Ovary: 1. Germinal epithelium normal.
2. Connective tissue normal.
3. Many primordial small and medium size follicles present and in normal condition. Several nearly mature follicles in normal state of preservation. A few atretic follicles.

4. Blood vessels normal.
Left Ovary: 1. Germinal epithelium normal.
2. Connective tissue normal.
3. Primordial small and medium size follicles normal. Several nearly mature follicles in normal state of preservation. A few atretic follicles.

RABBIT 9.—Killed eight weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.
2. Connective tissue cortex thin in some places, thick in others. About normal in amount.

3. Primordial follicles few and not affected. Small follicles fairly numerous; some degenerating, others normal. No follicles near full development not degenerated. A few large follicles in state of cystic degeneration.

4. Blood vessels normal.
Left Ovary: 1. Germinal epithelium normal.
2. Connective tissue cortex normal.

3. Primordial small, medium and nearly mature follicles normal. A number of atretic follicles present.

4. Blood vessels normal.
RABBIT 10.—Killed eight weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.
2. Connective tissue cortex normal.
3. A large number of primordial and small follicles in normal state. A number of atretic follicles.

4. Blood vessels normal.
Left Ovary: Fairly large, but smaller than the right.
1. Germinal epithelium normal.
2. Connective tissue cortex normal.
3. Many primordial and small follicles in normal state.

Fig. 7.—High power of nondegenerating follicle nine weeks after 600 mg. hours of radium.

Fig. 6.—A nearly mature nondegenerating follicle eight weeks after 500 mg. hours of radium; it shows an unusually developed theca.

Many follicles near maturity in normal state of preservation. Many atretic follicles.

4. Blood vessels normal.
RABBIT 11.—Killed eight weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.
2. Connective tissue cortex normal.

3. All follicles except the primordial and small follicles in a state of degeneration. A number of atretic follicles.

4. Blood vessels normal.

Left Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex normal.

3. Very few follicles of any size. No large follicles present.

4. Blood vessels normal.

RABBIT 12.—Killed nine weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex normal.

3. Primordial follicles few in number. Medium size follicles few. The nearly mature follicles all in a state of degeneration. The degeneration is more marked in the granulosa than in the ovum.

4. Blood vessels normal.

Left Ovary: 1. Germinal epithelium, connective tissue and follicles are as described in right ovary. There are a number of thin walled vessels filled with blood, a condition not seen in other ovaries examined.

RABBIT 13.—Killed nine weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex normal.

3. Few primordial and moderate number of medium size follicles. Large follicles all in state of degeneration.

4. Blood vessels normal.

Left Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex thin.

3. Few follicles of any size to be seen. One nearly mature follicle in state of preservation.

4. Blood vessels normal.

RABBIT 14.—Killed nine weeks after 600 mg. hours of radium.

Right Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex rather thin.

3. Very few primordial or small follicles present. A few nearly mature follicles in state of degeneration. Several large atretic follicles.

4. Blood vessels normal.

Left Ovary: 1. Germinal epithelium normal.

2. Connective tissue cortex normal.

3. Few primordial, many small follicles. A few medium size and a number of nearly mature follicles in normal state. A number of large atretic follicles.

4. Blood vessels normal.

RABBIT 15.—Killed nine weeks after 600 mg. hours of radium.

- Right Ovary: 1. Germinal epithelium normal.
 2. Connective tissue cortex normal.
 3. Many primordial and small follicles. No follicles of size to be affected by radium.
 4. Blood vessels normal.
 - Left Ovary: 1. Germinal epithelium normal.
 2. Connective tissue normal.
 3. Many primordial and small follicles, some normal, some degenerated. All follicles near maturity degenerating.
 4. Blood vessels normal.

ABSTRACT OF DISCUSSION

DR. HENRY SCHMITZ, Chicago: There is much difference of opinion as to how radium causes amenorrhea in the treatment of uterine hemorrhage, either idiopathic or myomatous. Most writers regard it as a destruction or degeneration of the ovarian epithelial cells. I believe that the effect of the radium is almost exclusively confined to the endometrium which receives in a twelve hour exposure of 50 mg. of radium element a burn of the third degree in some parts, a burn of the second degree in the parts more distant from the radium capsule and a burn of the first degree in the most distant lateral portions. A burn of the third degree causes an irreparable damage, while burns of the first and second degrees heal very readily with partial restitution of function in the endometrium. The action of the rays on the ovaries is negligible. I have examined microscopically many ovaries obtained by panhysterectomy in cases of carcinomatous uterus to which from 6,000 to 8,000, and more, milligram element hours of gamma rays had been applied. Macroscopically, a decrease in the size of the ovaries was noted; on section the ovary appeared to be hard and sclerotic and devoid of folli-

usual location of the radium capsule in these treatments. Supposing that the radium carrier is exactly maintained in this position, then according to the law of the inverse ratio the ovary receives one sixty-fourth the amount of rays the endometrium receives at 1 cm. distance. At 1 cm. distance from a radium capsule the lethal erythema skin dose is about

Fig. 9.—A follicle nine weeks after 600 mg. hours of radium. There is beginning degeneration in the granulosa, with a well preserved ovum. This degeneration is probably not the result of radium, as nine weeks have elapsed since treatment, and the changes are only beginning.

100 milligram element hours and at 8 cm. it is 64×100 or 6,400 milligram element hours. If this is divided by five, the ovarian sensibility quotient, then the amount of milligram element hours to cause degeneration of the ovarian epithelial cell elements, so that amenorrhea results, must be at least 1,280 milligram element hours. Hence, 600 milligram element hours, the amount usually used, cannot produce degeneration in the human ovary. Dr. Maury's findings and conclusions may also be proven by clinical observations. Many of these patients, after a period of amenorrhea lasting usually from three to six months, again menstruate regularly. Evidently, the damage in the endometrium was partly repaired and ovulation, not having been interfered with, begins to exert its influence on the repaired endometrium. Two patients, one treated for an essential menorrhagia, the other for a myomatous menorrhagia, soon after treatment conceived and had normal pregnancies and labors. The infants, also, were perfectly normal. These two instances prove beyond doubt that radiation did not affect the ovaries, or if it did, the injuries were not irreparable. The results of these animal experimentations would be beyond criticism if the erythema skin dose of the rabbit had been determined and the distance between the radium capsule and the ovary had been noted. If one of the ovaries had been removed in each rabbit first, and the one left behind treated immediately afterward, comparisons could have been made between the irradiated and the normal ovary in the same animal.

Fig. 8.—A well preserved follicle six weeks after 600 mg. hours of radium.

cles. Microscopically, a degeneration or absence of all epithelial cell structures was noted. The interstitial tissue or stroma was not affected. The sensibility of the ovaries to the rays in comparison to the erythema skin dose, which is taken as the standard in biologic measurements, is about five times greater. The ovaries are on an average about 8 cm. distant from the middle of the upper portion of the uterine cavity, the

The Ideal of Preventive Medicine.—Preventive medicine can never be satisfied until it has attained Isaiah's ideal (Isaiah lxx, 20): "There shall be no more thence an infant of days, nor an old man that hath not filled his days; for the child shall die an hundred years old."—Arthur Newsholme, *Commonwealth*, Nov.-Dec., 1919.

Clinical Notes, Suggestions, and New Instruments

APPARATUS FOR COLLECTING CARBON DIOXID SNOW

WILLIAM ALLEN PUSEY, M.D., CHICAGO

I am repeatedly called on for advice as to the best apparatus for collecting and molding carbon dioxid snow, or for information how to collect and mold it. These requests are still so frequent that it seems to me worth while briefly to describe the method which I have found satisfactory and

Apparatus for collecting carbon dioxid snow.

which requires only such apparatus as one can readily devise for himself. This method is as follows:

I use a piece of chamois skin to collect the snow. Two or three layers of towel or cloth can be used, but chamois is better. A piece of chamois skin about the size of a large handkerchief is a convenient size. The tank of liquid carbon dioxid is kept on a rack where it is slightly inclined with the nozzle at the lower end, so that the liquid carbon dioxid will be blown out when the vent is opened. To collect snow, the chamois is wrapped around the tip of the tank so that it bags over the vent but forms a fairly tight sack around the tip. If then the shut-off is opened by a turn of the wrench, carbon dioxid will escape into the chamois, and, if there is any liquid in the tank, will quickly collect as a mass of snow in the chamois. A very few seconds is sufficient to collect enough snow to make the ordinary stick. The vent is closed after a few seconds; the chamois unwound, and the snow can then be scraped up in a spoon to be put into the molds.

For molds I use metal or rubber tubing such as is shown in the accompanying illustration. A good length for the molds is about 3 inches. I keep a supply of molds varying in diameter from one-third inch to 1½ inches. For the smaller molds, which have to stand a severe strain from the pounding necessary to make hard sticks, seamless metal tubing is best; otherwise the tubing is likely to give way at the seam. For making large, thick sticks a rubber mold is sufficient, but it is not so good as a metal one. For convenience, on each mold that is frequently used I have attached a permanent funnel.

With the larger molds I push down the snow through a funnel like the two short molds, one of which stands at either side in front in the illustration. For molding the snow in the cylinders I have metal or wooden rods which correspond approximately in diameter to the diameters of the tubes in which they are used. The only other apparatus necessary is a hammer with which to drive down the snow with the rods.

The snow collects in the chamois in a loose mass. It is pressed down into the molds with the rods by hand as firmly as possible. This procedure is repeated with successive quantities of snow until the cylinder is well filled with a firm mass. Then it is hammered down with a hammer until a firm stick of snow is formed. In a tube of small diameter, one can hammer it down firmly enough to make a stick of ice; but ordinarily it is not desirable to have the stick so hard. In a minute or two after forming the stick, it becomes loose in the mold through evaporation, so that it can easily be pressed out of the mold. It is then handled between the fingers protected by a bit of chamois skin. After the sticks are made they can easily be shaped to any form desired by melting on a metal surface. For this purpose I keep a little nickle-plated flat-iron with the handle taken off. On this, carbon dioxid snow can be readily made in any desired shape.

The only difficulty about this method of molding the sticks is that one must have some solid base on which to pound. I have always done this on a corner of the top of a fire-proof safe. The advantage about this method of molding carbon dioxid snow is that it gives one a wide range in the size of the sticks that he can make. One does not always want the same size sticks. This method is convenient and it has entirely served my purpose.

7 West Madison Street.

A SIMPLIFIED PLATE METHOD OF PARTIAL OXYGEN TENSION IN THE CULTIVATION OF THE GONOCOCCUS*

RUSSELL D. HERROLD, M.D., CHICAGO

The idea of growing the gonococcus and other organisms under reduced tension is not new. Wherry and Oliver¹ have demonstrated the value of the method. Chapin² and more recently Maitra³ have used it with success in obtaining primary cultures on a variety of mediums.

The advantage of using plates in the isolation of the gonococcus is obvious when it concerns the isolation of gonococci mixed with other bacteria. Here, streaking of the material over a large surface is necessary to obtain discrete colonies. The simple method of using partial oxygen tension plates here described has been devised and employed with success in this laboratory.

Two inoculated plates, one with gonorrheal material, the other with *Bacillus subtilis*: at left, with open sides facing each other; at right, with edges enclosed by rubber band.

Two inoculated plates, one with the gonorrheal material, and the other with *B. subtilis*, are placed together with the open sides facing each other as shown at the left in the illustration. Then a closed rubber band 2½ inches wide by 3½ inches in diameter encircles both, enclosing the edges but allowing aerial communication between them, as shown at

* From the John McCormick Institute for Infectious Diseases.

* This work was carried out by means of a grant from the United States Interdepartmental Social Hygiene Board.

the right. Satisfactory bands may be obtained by cutting wide rubber tubing into pieces of the required width. The simplicity of this method makes it practical for the small laboratory and, in addition, permits of individual cultures being examined without disturbing others, as is necessary with several cultures in a single jar. The rubber also serves equally well for air exclusion plates, which have a distinct advantage over open aerobic plates in gonococcus cultivation; but they are inferior to the partial oxygen tension method just described, especially in obtaining primary growth. Parallel plates have been tested with a variety of mediums, and the best growth was obtained on nutrient bactoveal agar in which dibasic sodium phosphates were substituted for sodium chlorid.⁴ Ascites fluid and defibrinated goat blood were added in the approximate proportion of 2 c.c. of ascites fluid and 0.5 c.c. of blood to each Petri dish before pouring the plates. A fair growth has resulted with this medium minus ascites fluid.

Cultures of gonococci have been obtained in several cases of chronic infections in which the gonococcus could not be identified in smears. In all the acute cases of gonorrheal urethritis there was a profuse growth, parallel aerobic plates showing fewer and smaller colonies.

Recently this scheme has been used in place of the culture of *B. subtilis* with good results: A quantity of sodium bicarbonate is placed in the Petri dish instead of the culture of *B. subtilis*, and at the same time a small glass tube containing 0.5 c.c. of 1 per cent. sulphuric acid is introduced so that when the plates are enclosed in the rubber band the two chemicals come into contact with each other. In this way sufficient carbon dioxid is liberated to produce a favorable tension.

ACETANILID ADDICTION: REPORT OF A CASE

WALTER H. NADLER, M.D., CHICAGO

This case is of clinical interest because of difficulty in diagnosis, aggravated by persistent denial of drug addiction and by malingery on the part of the patient.

REPORT OF CASE

History.—Miss X, graduate nurse, aged 26, was admitted to Wesley Memorial Hospital, Oct. 20, 1919, complaining of attacks of pain in the left hypochondrium, and of chills and fever. The pain was sharp, was transmitted to the back, and had recurred at intervals of about three weeks over a period of two years.

The course of her illness may be divided into two periods. The first period, from 1909 to 1915, consisted apparently of recurrent nose, throat and accessory sinus infections, and of anemia. During this time, tonsillectomy, turbinectomy, frontal sinus and left mastoid operations and drainage of an appendical abscess were performed. From 1915 to 1917 seems to have been an interval of fair health. The second period, from January, 1917, to the present time, is characterized by an entirely new group of symptoms. While the patient was still in bed, following an operation for the relief of apparent intestinal obstruction, cyanosis appeared, together with dyspnea on exertion. During convalescence from a second operation in the left mastoid region, she was seized with sudden, severe pain in the left upper abdomen, followed by fever. The urine was scant and dark colored. Cyanosis had been continuously present, though of variable intensity, since that time, and attacks of pain had recurred at rather regular intervals. For the relief of these symptoms, she submitted to an exploratory laparotomy and a kidney operation. Hospital records indicate that nothing abnormal was found and that no relief was afforded. In view of her occupation and the use of narcotics after her formidable series of operations, the patient was particularly interrogated in regard to the use of drugs. Any such habit was earnestly denied.

Examination.—The patient was intensely anemic and cyanotic, well nourished, apparently febrile and in great pain. The temperature was 103, the pulse and respirations

normal. The sclerotics and the oral mucous membranes were definitely icteric. Scars of the operations described were present. Marked tenderness and slight involuntary muscle defense in the left hypochondrium were noted. The liver and spleen were not palpable. Atrophic rhinitis with an accumulation of scabs was reported as a possible atrium of infection. Roentgen examination of the chest and gastrointestinal tract detected nothing abnormal save a limited excursion of the diaphragm, not due to adhesions, on the left side.

The urine, which was reddish brown, contained urobilin and much unidentified sediment, but appeared otherwise normal. The blood serum, also reddish brown, contained neither hemoglobin, bile salts nor pigment (Gmelin test); the Wassermann test was negative. Hemoglobin, in spite of the obviously anemic appearance, was estimated as from 95 to 100 per cent., probably because of the dark color of the serum. The red blood count was 3,180,000, and the white count, 11,800. Blood smears showed slight poikilocytosis and the general appearance of secondary anemia.

Clinical Course.—After the first week in the hospital, during which the afternoon temperature was recorded as from 103 to 104, it became apparent that the fever was simulated, the desired reading being produced through the aid of a hot water bag. At the same time, it was suggested by Dr. E. L. Ross that the clinical picture resembled that of acetanilid poisoning. Examination of the urine revealed the presence of acetanilid. Methemoglobin was not definitely detected in the blood serum.

Cyanosis gradually disappeared, but after five or six days reappeared. Use of the drug was again denied, but, confronted with her written order to a neighboring druggist, the patient surrendered acetylsalicylic acid and acetanilid tablets and admitted that she had taken six of the latter. Confession was finally made of the use of acetanilid, to 50 grains a day, over a period of nearly three years. Use of the drug antedated the appearance of pain in the left side; it was begun for the relief of headache and pain following her early operations. During the remaining weeks in the hospital, cyanosis and icterus disappeared; the urine and blood serum became of normal color, and no attacks of pain occurred. November 17, the patient was discharged from the hospital apparently well, except for persistent slight tenderness in the left hypochondrium.

The following day she applied for admission to the Cook County Hospital, complaining chiefly of pain, weakness and dyspnea. After a period of observation, anemia due to long continued hemolysis caused by numerous infections was suspected. Cyanosis was noted, November 23. Attacks of pain recurred at regular intervals; opiates were administered. Finally, malingery of fever and of certain other symptoms was detected. March 18, the patient was discharged, feeling well enough to go to work. All of the symptoms were explained on a neurotic basis except the cyanosis and slight icterus, which were considered probably due to acetanilid or a similar hemolytic drug.

COMMENT

The symptoms are those of the definite complex characteristic of chronic poisoning due to acetanilid, which is recognized as a habit-forming drug.

30 North Michigan Avenue.

Health Education.—During the year the necessity for health education among teachers has become more evident and courses on the care of mothers and children for use in colleges and normal schools are being prepared under the Federal Board of Vocational Education. Undoubtedly the revelation of our recent draft rejections, showing that at least one half the defects were such as might have been eliminated in childhood, has added impetus to the interest in the physical condition of our children; and the supplementary evidence of malnutrition and defects, as brought out by the weighing and measuring test, has helped focus public opinion on physical fitness.—*Am. J. Pub. Health* 9:350, 1919.

HEMOGLOBIN AND CARBON DIOXID

The oxygen-carrying power of hemoglobin has been so widely studied and seems to be so well understood that little attention has been given to this pigment in relation to the movement of other gases in the body. Up to comparatively recent times, the transport of carbon dioxide in the organism has been attributed to the inorganic salts of the plasma, notably the bicarbonate. The rôle of other potential carriers, such as the proteins, has been emphasized more or less, while Buckmaster and Bayliss have even attributed the entire transport of carbon dioxide to hemoglobin directly. The problem of how the bound carbon dioxide could be released from the bicarbonate or protein combination in the lung has been a stumbling block in the theories, although the older workers recognized in the acid properties of hemoglobin a possibility of causing the unloading of carbon dioxide in the lung. As a matter of fact, hemoglobin, with its iso-electric point at p_H 6.7, is always acting as an acid under the conditions of hydrogen ion concentration in the blood. Some such acid liberating agent must be present in the lung, for the mere decrease of carbon dioxide tension from that of the tissues to that of the alveolar air would not cause the gas to pass off from the carbon dioxide-bicarbonate system of the plasma.

Parsons¹ has shown that the concentration of base in the blood is sufficient to account for all of the carbon dioxide to be carried as bicarbonate. In addition, he demonstrated that another weak acid must be present in the lung to aid in the unloading of the carbon dioxide by competing for the base of the bicarbonate. This acid, *a priori*, must be one whose salt with the base is decomposed by such concentrations of carbon dioxide as occur in the tissues. Parsons states that the proteins act as such an acid in the blood, and that the chief among these is hemoglobin.

L. J. Henderson,² elaborating somewhat on Parsons' work, has shown that in hemoglobin in the blood

we have the unusual case of an acid which, under stress of circumstance, alters its degree of dissociation. Obviously, the circumstance is the presence of oxygen. In the lung, hemoglobin which, as stated above, acts as an acid in the blood, combines with oxygen, and immediately its ionization is increased and its power to bind base is accordingly increased. This base is at hand in the bicarbonate, and on combining with the oxyhemoglobin it leaves the carbon dioxide free to be blown off. In the tissues the oxygen leaves the base-oxyhemoglobin combination, and the hemoglobin, returning to its feeble degree of ionization, loses the base, which is then free to help carry the carbon dioxide back to the lung as bicarbonate. Henderson also states that the other proteins as well as the phosphates take part in transferring base from the lung to the tissue.

Parsons³ adds that the variation of hydrogen ion concentration under the influence of carbon dioxide, as it occurs in the blood, requires the presence of a slightly ionized acid, such as hemoglobin. In addition to its other functions, hemoglobin thus functions as a buffer. It appears, therefore, that from the latest theoretical considerations of well-known data the hemoglobin of the blood not only acts as a carrier of oxygen throughout the organism, but also plays an important part in the transport and release of carbon dioxide in the body.

ORANGE JUICE CONSIDERED IN A NEW LIGHT

It is recognized by pediatricians that artificially fed infants thrive better if they receive some addition to cow's milk, particularly when the latter is pasteurized or sterilized. One reason for this, now understood, is that many of the artificial food mixtures are likely to be qualitatively incapable of averting scurvy in young children, so that some added antiscorbutic must be provided. For this purpose orange juice has attained a well deserved popularity. Other fruit juices have likewise been used with success as antiscorbutics; and latterly the juices from certain vegetables have been demonstrated to have a similarly beneficial influence in the dietary of the young. Owing to the price and occasional scarcity of oranges, notably during the war, special efforts were made, both here and abroad, to secure suitable substitute antiscorbutics for infant feeding. The use of the tomato, first urged by A. F. Hess of New York, has been particularly promising owing to the fact that, in contrast with some other antiscorbutics, this readily available vegetable can be dried or canned without losing its potency in antiscorbutic vitamin, and it can be administered efficiently in various ways, including intravenous injection of the juice.

1. Parsons, T. R.: The Reaction and Carbon Dioxide Carrying Power of Blood—A Mathematical Treatment, *J. Physiol.* **53**: 42 (Sept.) 1919.

2. Henderson, L. J.: The Equilibrium Between Carbon Dioxide and Oxygen in the Blood, *J. Biol. Chem.* **41**: 401 (March) 1920.

3. Parsons, T. R.: The Reaction and Carbon Dioxide Carrying Power of the Blood—A Mathematical Treatment, *J. Physiol.* **53**: 349 (Feb.) 1920.

From the recent investigations of Osborne and Mendel it appears that the tomato has even further properties to commend its use during the period of growth; for it is rich in the water-soluble antineuritic vitamin,¹ and likewise in the fat-soluble vitamin² (fat-soluble A) characteristic of milk fat and egg fat. Such observations, along with numerous others of recent date indicating how widespread is the fat-soluble vitamin in vegetable products,³ show that this important food factor need not be sought solely in foods known to be rich in fats. As Osborne and Mendel have remarked, the newer studies indicating the richness of many types of plant tissues in those nutritive properties termed vitamins place the dietary importance of the green vegetables in an entirely new light. It emphasizes their use to supplement the refined foods of the modern food industry which furnish products rich in proteins, fats and carbohydrates but in many cases comparatively deficient in the vitamins. The tomato is striking in exhibiting all the now recognized vitamin potencies; the antineuritic, antiscorbutic and the fat-soluble vitamin. Little wonder, then, that it has found an important place in the dietary.

Orange juice has also now been shown to be possessed of something more than attractive flavor and antiscorbutic virtues. The same observers⁴ have demonstrated the presence of the water-soluble B, the antineuritic vitamin, in both the juice and the inner peel of the orange—a finding promptly corroborated by Byfield and Daniels⁵ at the University of Iowa. Evidently, therefore, when orange juice or tomato is added to the food of an infant, something more than an antiscorbutic is furnished. The Iowa pediatricians have noted that in every case when the antiscorbutic dose of orange juice, 15 c.c., was increased to 45 c.c. a day to infants whose weight had remained stationary for a number of days, there was a marked stimulation of growth. A mere increase of food intake (calories) of itself had no such influence on the rate of gain.

Orange juice from which the antineuritic vitamin (water-soluble B) is removed by adsorption⁶ does not thus stimulate growth, although it still has antiscorbutic properties. This answers the assertion that the antiscorbutic vitamin may be responsible for promotion of growth. In feeding orange juice, provided the quantity is not too small, one is administering at

least two highly beneficial adjuvants to the diet. This fact, and the growing practice of early enlarging the diet of milk fed infants by the use of fruit juices, etc., is significant further in view of the recent demonstration by Osborne and Mendel⁷ that cow's milk, from a comparative standpoint, is not rich in water-soluble vitamin. Osborne and Mendel have pointed out how recent studies of the antiscorbutic value of cow's milk⁸ have indicated that on this score it must be classed as less valuable than many of the raw fruits and vegetables. Whereas quantities of the latter—less than 10 gm. daily—will prevent scurvy in guinea-pigs on a diet otherwise devoid of antiscorbutic material, from 100 to 150 c.c. daily of raw cow's milk are required for this species, according to Barnes and Hume, while monkeys require larger quantities. Similarly, relatively large quantities of milk are required to produce the increased intake of food and improved rate of growth which are readily secured by very small quantities of many green vegetables.

IMMUNIZATION AGAINST PLAGUE: AN ARGUMENT FOR CONTROLLED EXPERIMENT

The reiterated plea of scientists for accurately controlled experiments in the determination of the value of measures adopted against disease may seem to some physicians to be somewhat too emphatic. Again and again, however, the disinterested scientist is compelled to protest against the use of statistics and experiments by those commercially interested and by overenthusiastic advocates of the prophylactic use of certain products. How difficult it really is to arrive at definite conclusions relative to the efficacy of many such preventive measures is pointed out by Flu,⁹ in a recent discussion of experiments on immunization against plague. The reports concerning the results of vaccination against this disease have been contradictory. Haffkine believed that he had demonstrated statistically that his vaccine was effectual in creating immunity. Bitter and other observers, analyzing the work of Haffkine, concluded that the immunity acquired was not of high degree and that it did not last more than six months. That opinions based on statistics may not be reliable, Flu illustrates by the recital of an incident occurring in the Division of Malang in Java:

During the epidemic in the division of Malang (Java), when thousands of plague cases were occurring monthly among the inhabitants of kampongs and desa's, only one single case of plague occurred among the soldiers of the garrison in the capital Malang, being a thousand strong, in the four years the plague was raging there. This one case, was a

man with a bubo in the neck who had not been infected at the barracks, as could be ascertained almost absolutely. If at the beginning of the epidemic the garrison in Malang had been vaccinated against plague, and if the results of that measure had been judged by comparison between the numbers of plague cases among the vaccinated soldiers and among the inhabitants of Malang, then this single isolated case among the former compared to the many thousands among the latter, apparently would prove for the advantage of the vaccination. This conclusion, however, would not be admissible for a local investigation would show that the soldiers in Malang are living under much better and more hygienic circumstances than the best situated inhabitants of the kampong.¹⁰ The fact that the soldiers were not attacked would prove being due not to the vaccination but to the favorable conditions in the barracks, that exclude a tight contact of man and rat.¹⁰

Flu is able to recite other instances in which incomplete reports of plague epidemics might well be cited as strong evidence of the efficacy of the various measures employed in prophylaxis. One example is an epidemic that occurred in the *desa* (village) of Sempal Wadak in Malang, a place of about 1,700 inhabitants, in which a large sugar factory is situated. At the time of the epidemic, there were about fifty European assistants, and about 300 native laborers employed there:

In the *desa* the plague was raging most heavily, 80 cases occurring there during three months. Suppose, that the Europeans had had themselves vaccinated against plague with f. i. [for instance] HAFKINE vaccine, and that by their influence they had persuaded the natives to have done the same. Now, if only was [it were] mentioned how many people were vaccinated at Sempal Wadak and how many not, and if further was said that among the Europeans only one single case of plague occurred, while among the native labourers of the factory two cases occurred against 80 cases among the not vaccinated inhabitants of the *desa*, it would wrongly appear as if the vaccination had been of excellent service. Really, these figures would not prove anything. For the Europeans were living in houses that were well protected against visits of rats and were built ratnestproof. Also the labourers of the factory came up to the requirements ordered by the house-improvement service. The only European infected had had to stay in a village-house, his own house being repaired: during his stay in the not improved village-house he was infected.

Because of such instances as these, epidemiologists have begun to be skeptical concerning statistics that are cited without the presentation of all the details necessary for an accurate judgment. The many factors entering into the causation of disease: age, sex, race, social status, occupation, residence, hygiene, house conditions—all have a definite influence. It is only by careful and repeated consideration and the employment of numerous controls that the relative importance of each factor can be estimated in any degree approaching accuracy.

As a result of his consideration of the subject, Flu determined that the only experiments on plague that can be considered of any real value are those on animals, since it is impossible to secure perfectly controlled conditions in such work on man. Experiments of this kind he carried out in great detail, using

large numbers of animals. Of all the vaccines examined, only the aqueous extracts were found to have any definite immunizing power. However, as only a low percentage of immunized animals survived injections with large doses of bacteria, he concludes that the expectation that in the course of time some method of immunization against plague may be found which will be effective in 100 per cent. or even 90 per cent. of the cases treated is at present absolutely in vain. That this is the case is supported by the fact that even a natural infection of this disease is not capable of conferring definite immunity.

Current Comment

REPUBLICAN PLATFORM AND HEALTH AND EDUCATION

In the General News column¹ appears the full text of the plank on education and health adopted last week by the Republican convention. The association of these two subjects in a single section is significant of the increasing realization of the close relation and mutual interdependence of health and education. Good health either of the individual or of the community is largely a matter of education. All true education results in better health. In the joint development of these closely allied activities there is room and need for the specialist and expert in both fields. Possibly most of our readers will be especially interested in the paragraph that points out that the health activities of the federal government are scattered through numerous departments and bureaus, resulting in inefficiency, duplication and extravagance. It very wisely limits its recommendations to greater centralization of federal functions and better coordination of federal, state and local agencies, without attempting to discuss the exact method by which this result is to be secured. The reorganization and extension of federal public health work has been under discussion for half a century. While all are agreed as to the desirability of such expansion, there is no unanimity as to the exact method by which it should be accomplished or the form it should take. These questions can be answered only after careful study of existing conditions in order to determine what the federal government is now doing for public health, how much is being expended and what is being accomplished, what are the public health functions which belong to the federal government, what are those which belong to the state, and how coordination can be best effected. These are not questions for either partisan or sectarian controversy but rather for patient study and constructive planning. Whatever may be our differences of opinion as to the peace treaty with Germany, the League of Nations or the high cost of living, all good citizens are agreed as to the importance of both education and health. It is to be hoped that the Democratic convention at San Francisco will make an equally broad and constructive declaration on these two subjects.

¹⁰ The periodical from which this quotation is taken is published in Java; each page contains two parallel columns, one Dutch, the other English. The English is not always strictly grammatical, as will be noted from the portions cited.

PUBLIC HEALTH POETRY

Poets, we are told, are born, not made. But every one has a sense of rhyme and rhythm. Rhyme and rhythm aid memory—they have “catchy” qualities. As a result we have not only spring as the open season for poets but also a year round open season for the public health poet. He takes a simple hygienic slogan, such as “Flies breed disease—swat ‘em,” and turns out poetry of a practical sort:

“The fly, also, is a nuisance, very small,
The greatest pest, I’m sure, of them all.
In the daytime it is humming, humming though it
has no song,
If the city is kept clean, it will disappear ere long.”

See how easy it is to write “poetry.” One merely measures off so many centimeters of line and puts a big letter on the front. Let us suppose it is desired to inform a nervous public that mosquitoes carry malaria. Does the public health poet hesitate?

“Did you know mosquitoes bring
Other things besides their sting?
Sometimes when they bite, they leave you
With malaria or with fever.
Dry up all the stagnant places—
Breeding places of all their races;
Keep your screen doors closed, and fling
Defiance to Sir Skeeter’s sting!
Let your slogan through the summer
Be to kill this wicked hummer.”

Simple, isn’t it? Yet it gets there all the same. But the subjects have been too broad, too indelicate! Now for something really practical and esthetic:

Oh! blessings on the garbage man:
He comes around and gets our can;
He cleans it up quite nice and neat—
Then it leaks out of his wagon and is scattered all
over the blooming street.

ANTHRAX AND THE SHAVING BRUSH

Previous to 1914, anthrax infection in nearly all instances occurred only among those who came in contact with cattle, hides, meat or wool; but soon after the outbreak of the war, numerous cases appeared among persons who had not been associated with any of the usual known sources of the disease. From time to time, outbreaks of anthrax developed among soldiers of both England and the United States, and careful investigation revealed that nearly all cases developed from shaving wounds. It was later found that certain types of shaving brushes harbored virulent anthrax bacilli. Shaving brushes used in this country are for the most part made from badger hair, horsehair or pig bristles, though much of the so-called badger hair is an imitation made by treating white hair or bristles. Until the war, nearly all the horsehair and pig bristles came from Russia, China and Japan, after being cleaned and disinfected in France or Germany. But after 1914 they were shipped directly to this country by the Pacific route. With the advent of the war, the unusual demands on the shaving brush industry necessitated such a rapid output that some manufacturers, through ignorance, carelessness or too great confidence in the certificates of disinfection, made no effort to

insure the safety of the material used. The horsehair from China is notoriously dirty, very likely anthrax-infected, and shipped with “no indication of manner or methods of treatment.”¹ Domestic hair dealers, principally in Chicago, wash the hair with soap or lye in warm water, but there is no established method to make the hair safe from anthrax. A number of these cleansing processes were investigated;¹ some were found to be thoroughly satisfactory, others certainly offered no guarantee of safety, and there is no doubt that there are now on the market many brushes potentially dangerous, most of these being of the cheaper grades. At present the methods of disinfection used by the manufacturers of shaving brushes are not standardized, and many are inefficient. In England from June, 1915, to October, 1916, fourteen cases² of anthrax infection are known to have originated from shaving brushes. In nearly all instances a recently purchased brush had been used a few days before the appearance of the malignant pustule. Virulent anthrax bacilli were found on the patient’s brush and on others obtained from the same lot. A rather low human susceptibility was indicated by the fact that only one case is known to have developed from a lot of 10,000 brushes, though anthrax bacilli were found in all samples examined. In this country, twenty-four cases of anthrax from shaving brush infection³ have been recorded; in six instances the bacilli were isolated from brushes used. It is of interest to note that several cases of meningitis were encountered, anthrax bacilli being isolated from bloody spinal fluid. In three instances, no evidence of an external lesion was found. In thirty-three cases of shaving brush anthrax, twenty-one, or 64 per cent., of the patients died;⁴ this high mortality may be due to the site of infection, wounds of the neck being more serious than elsewhere. By the use of proper methods, anthrax infection from shaving brushes is entirely and easily preventable. Systematic inspection and definite requirements of sterilization will eliminate the shaving brush as a source of anthrax infection. Boiling, exposure to streaming steam, or soaking the material for four hours in 10 per cent. dilution of liquor formaldehydi at 110 F. are said to be reliable methods of disinfection.

4. Footnote 2, first reference.

Increase in Automobile Accidents.—According to the annual report of the National Highways Protective Association, the total toll of life taken by motor cars throughout New York State during 1918 was 969 persons. The death list in New York City was 528, as against 417 for 1917. Of 441 fatal accidents that occurred outside the metropolitan area, 416 occurred between April 1 and December 31, and only twenty-five between January 1 and March 31. The president of the National Highways Protective Association recommends a law for New York State similar to that in Massachusetts, Connecticut, New Jersey and Maryland, which in New Jersey has been responsible for cutting down the number of fatal accidents from 245 in 1917 to 197 last year.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Graduate Courses in Hygiene.—The University of Alabama is establishing a department of hygiene in which graduate students will be prepared to teach hygiene and health conservation in colleges, normal schools or other like institutions. Satisfactory completion of the course will qualify for the degree of Bachelor of Science in Hygiene. There is immediate need of such graduates in the school health activities of the state. Dr. Hiram Byrd, formerly director of the department of hygiene in the University of Mississippi, is head of the new department.

ARKANSAS

Personal.—Dr. Keith E. Hudson, Dahome, has announced his retirement from the practice of medicine.—Dr. Fergus O. Mahoney has been elected president, and Dr. H. H. Niehuss, secretary, of the Eldorado Board of Health.

District Society Organized.—Greenwood District Medical Society was recently organized, with an initial membership of seventeen, and the following officers were elected: president, Dr. George G. Woods, Huntington; vice president, Dr. Bert L. Ware, Greenwood, and secretary-treasurer, Dr. Charles W. Hall, Greenwood.

State Isolation Hospital Planned.—The leaders of the public health movement in Arkansas are planning to build and equip a state isolation hospital and venereal disease clinic which will not only provide treatment, isolation and detention for commercial prostitutes in all places of the state where there are no clinical facilities or means of isolation, but will also give treatment in all cases of venereal infections in persons committed to the girl's industrial school and to the woman's reformatory.

State Society Election.—At the annual meeting of the Arkansas Medical Society held at Eureka Springs, June 8 and 9, under the presidency of Dr. George S. Brown, Conway, the following officers were elected: president, Dr. Gus A. Warren, Black Rock; vice presidents, Drs. Robert Howard Huntington, Eureka Springs, Andrew J. Clingan, Lockesburg, and Thad Cothorn, Jonesboro; secretary and editor of the *Journal of the Arkansas Medical Society*, Dr. William R. Bathurst, Little Rock (reelected); treasurer, Dr. Henry H. Kirby, Little Rock. Hot Springs was selected as the place of meeting for 1921.

FLORIDA

Personal.—Dr. Lorin A. Greene, Greenville, has been appointed superintendent of the new Florida Colony for Feebleminded and Epileptics.—Dr. William J. Buck, Jacksonville, has resigned as assistant state health officer.

New State Officers.—At the forty-seventh annual meeting of the Florida Medical Association held in Daytona, May 12 and 13, under the presidency of Dr. Ralph N. Green, Chhattahoochee, the following officers were elected: president, Dr. William E. Ross, Jacksonville; vice presidents, Drs. Clyde C. Bohannon, Daytona, George A. Davis, De Land, and James H. Fellows, Pensacola, and secretary-treasurer, Dr. Graham E. Henson, Jacksonville. Pensacola was selected as the next place of meeting.

Venereal Disease Clinic Established.—Seminole and Gadsden counties have joined hands with the state board of health, in its efforts to establish a venereal disease clinic in each of the counties of the state. The Seminole County Clinic is in operation at Sanford, and the Gadsden County Clinic at Quincy. Ten clinics are now in operation, the stationary clinics being located at Key West, Miami, Tampa, Arcadia, West Palm Beach, Jacksonville, Pensacola, Lake City and St. Petersburg in addition to an ambulatory clinic under the charge of Dr. John C. Bertram, Jacksonville.

Possible Deaths from Bubonic Plague.—The state laboratory, on June 13, announced that the death of George Gardina in Pensacola, June 11, was undoubtedly due to bubonic plague and that steps had been taken for an immediate cleanup campaign. Health officials of the state have determined on

a thorough extermination of rats.—The officials of the Public Health Service in Washington, D. C., say that it has not yet been definitely established that a case of bubonic plague had developed in Pensacola.—A second case of bubonic plague was officially reported to the authorities of Pensacola, June 15. The patient is an ice wagon driver, and his duties took him through the section of the city where the first case was discovered.

ILLINOIS

Chicago

New Officers.—Dr. John S. Nagel was elected president-elect, and Dr. Hugh N. MacKechnie, secretary of the Chicago Medical Society at the annual election, June 16.

Northwestern Alumni Meeting.—At the annual meeting of the Northwestern University Alumni Association held in Chicago, June 14, the following officers were elected: president, Dr. Franklin H. Martin, '80; vice presidents, Drs. John F. Williams, '65, and Robert Blessing, '20; secretary-treasurer, Dr. James G. Carr, '02, and necrologist, Dr. Samuel C. Stanton, '92 (reelected).

Guthrie Memorial.—At the meeting of the council of the Chicago Medical Society, June 8, a resolution was adopted providing that a proper inscription setting forth the facts of Dr. Samuel Guthrie's discovery of chloroform be placed on the glacial boulder at the entrance of Washington Park, at Garfield Boulevard, known as the Guthrie Stone. This resolution was referred to the committee appointed last year regarding the Guthrie memorial.

University of Illinois Alumni Meeting.—The annual meeting of the Alumni Association of the College of Medicine of the University of Illinois was held in Chicago, June 5, and the following officers were elected: president, Dr. Karl Meyer, '08; president-elect, Dr. Louis J. Hammers, '02; vice presidents, Drs. William H. Bradley, '10, Charles H. Hallberg, '11, and William B. West, '06; secretary and treasurer, Dr. John M. Krasa, '13 (reelected); and necrologist, Dr. O. McWilliams, '99.

MAINE

District Health Officers' Ranks Completed.—By the appointment of Dr. Adin L. Smith, Machias, as district health officer for Hancock and Washington counties, the roll of district health officers of Maine is completed, making a total of eight for the state.

Public Health Association Reorganized.—The work of the Maine Anti-Tuberculosis Association has been transferred to the newly organized Maine Public Health Association, which at its recent meeting in Bangor elected the following officers: president, Dr. Elmer D. Merrill, Foxcroft; vice presidents, Mr. E. M. Hamlin, Milo, Dr. Sylvester J. Beach, Augusta, and Mr. Henry Richards, Gardiner; executive secretary, Mr. W. A. Harris; secretary, Mrs. Howard Ives, Portland, and treasurer, Mr. Ralph Whittier, Bangor. The reorganization was undertaken for the purpose of entering a broader line of work than was possible under the old name and by-laws. Now prenatal care, child welfare and venereal diseases as well as tuberculosis work will be included in its program. One aim in the reorganization is to unify under one head all private health organizations of the state as rapidly as possible and to work more closely with the state department of health, school department, department of charities and corrections and other departments.

MARYLAND

Patients Ordered to Fort McHenry.—Dr. Charles W. Vogel, in charge of the United State Marine Hospital, Baltimore, has received orders from the Surgeon-General, U. S. Public Health Service, to transfer all patients and personnel to the public health hospital at Fort McHenry. The hospital at Fort McHenry is not ready to receive patients, but every effort is being made to put it in order and at the latest it is expected to be ready by July 15. The future fate of the Marine Hospital has not yet been determined.

Gift to Johns Hopkins.—A gift of \$400,000 has been made to the General Education Board of the Rockefeller Foundation Fund for the establishment of a department of pathology at the Johns Hopkins Medical School, and is the second appropriation of that amount to the school in less than four months. An appropriation of like amount from the same source was announced for the establishment of a women's

clinic at the hospital several months ago. The present fund is given contingent on the university's raising an additional \$200,000 toward a \$600,000 fund. The present gift is to be used in rebuilding the pathologic department which was destroyed by fire last January. Work on the new pathologic department will be started as soon as the additional \$200,000 is raised by the university.

Infectious Hospital Planned for Baltimore.—An ordinance submitting to the voters of Baltimore in November a loan of \$750,000 for an infectious disease hospital has been introduced in the city council. The loan was authorized by the legislature of 1914, but was pigeon-holed by the former administration. It was resurrected by Dr. C. Hampson Jones, health commissioner, who considers the hospital one of the pressing needs of the city. It is estimated that the municipal hospital will cost approximately \$1,000,000 to start with. The city is soon to receive \$177,000 from the federal government for the quarantine station. This added to the \$750,000 from the loan, if approved, will give the health department sufficient money for its needs. It is understood that the medical fraternity is solidly behind the hospital loan and that their influence will aid the public improvement loan materially.

MASSACHUSETTS

New State Officers.—At the one hundred and thirty-ninth annual meeting of the Massachusetts Medical Society held at the Boston Medical Library, June 8 and 9, Dr. Alfred Worcester, Boston, was elected president; Dr. Frederick E. Jones, Quincy, vice president; Dr. Walter L. Burrage, Boston, secretary (reelected); Dr. Arthur K. Stone, Framingham Center, treasurer; Dr. Edwin H. Brigham, Brookline, librarian.

Physicians Oppose Bill for State Maternity Aid.—In a circular letter to members of the legislature, four medical societies in the state, namely, the Worcester North District, Worcester South District, Franklin District and Fitchburg medical societies declare their opposition to the passage of a bill to provide maternity benefits for needy expectant mothers. This proposed legislation is considered as paternalistic and class legislation and as an infringement on the rights of individual citizenship.

MISSISSIPPI

Home for Feeble-minded.—Meridian is making strenuous efforts to obtain the location of the proposed state colony for the feeble-minded, to secure which, a donation of \$100,000 and a 1,000 acre site are essential.

Typhoid Vaccine Available.—Dr. Clyde R. Stingily, Jackson, bacteriologist of the state board of health, announces that he has now a sufficient quantity of typhoid vaccine for 30,000 cases and is ready to ship this to physicians of the state free of all expense.

NEBRASKA

Hospital Transferred.—The new Lord Lister Hospital, Omaha, has been taken over by the Danish Hospital Association. The institution will open this month and will have accommodation for 150 patients.

Alumni Meeting.—The annual meeting of the John A. Creighton Medical College Alumni Association was held, June 2 to 4. During these days, clinics were held at St. Joseph's Hospital, and on June 4, Dr. Henry S. Plummer of the Mayo Clinic delivered an address on "The Function of the Thyroid Gland."

Graduate Clinical Week.—A graduate clinical week was held, June 7 to 13, at the University of Nebraska, College of Medicine, Omaha. Emphasis was placed on social diseases as subjects for study and demonstration. Daily ward walks through the university hospital, and laboratory work in clinical pathology were some of the practical features of the week.

NEW YORK

Encephalitis Made Reportable.—Lethargic encephalitis has been added to the list of reportable communicable diseases by action of the public health council of the state department of health.

Tuberculosis Lecture Outline.—An outline of a lecture on tuberculosis for use before lay audiences in connection with the set of lantern slides belonging to the state department of health is now available and may be obtained by writing to the supervisor of exhibits, state department of health, Albany.

Health Clinics.—The New York State Department of Health in cooperation with the state department of education, state hospital commission, state committee for mental defectives, tuberculosis committee of the state charity aid association, and Atlantic Division of the American Red Cross inaugurated a series of group medical consultation clinics held at the Village Hall of Geneseo, June 8, 9 and 10.—At the clinic held in Rome, May 12, by Dr. Sydney F. Blanchet, Saranac Lake, twenty-five persons were examined for tuberculosis.

New York City

Personal.—Dr. George D. Wolf has been appointed adjunct professor of otology and rhinology in the Bronx Hospital and Dispensary.

Guarding Against Plague.—Owing to the outbreak of bubonic plague in Vera Cruz, the health authorities of the city are acting in cooperation with Dr. Leland E. Cofer, health officer of the port, in an effort to strengthen the lines of defense against the importation of the disease. Cyanid is being used for fumigation of all vessels from any suspected port. A careful sanitary inspection is being made of all city piers.

Milk Charity Transfer.—Nathan Strauss, before sailing for Palestine where he expects to devote himself to relief work, on June 11, made a statement to the mothers of the city of New York stating that he felt that his task of furnishing pasteurized milk to the babies of New York was finished, and that his milk stations would be discontinued after September 1. The work will be continued during the summer, he says, in order to give mothers the opportunity to visit his laboratories and learn methods for the home modification of milk. He has offered to turn over to the city his milk laboratory complete, with all its equipment and motor trucks, provided the city supplies funds to maintain and expand the work.

Tuberculosis Activities.—The first public meeting of the New York Tuberculosis Association was held, May 18, Dr. James Alexander Miller, presiding. Dr. Miller told of the work for the vocational training of soldiers and sailors who have now been transferred to civilian control; Mr. Fred M. Stein explained in full the plans of the workshop to be established in Long Island City; Mr. T. B. Kidner of the National Tuberculosis Association spoke on the "Rehabilitation of Consumptives to Industry"; Dr. C. Floyd Haviland, Middletown, Conn., delivered an address on "Occupation and Treatment in Convalescence," and Dr. John S. Billings presented the plan of the association for the reconstruction of the consumptive. This includes an application bureau as a part of its information bureau, and an employment bureau. A group of the larger sanatoriums in the vicinity of New York City have agreed to cooperate with the association by establishing schools for the vocational training, especially of service men.

OHIO

New State Officers.—At the seventy-fourth annual meeting of the Ohio State Medical Association held in Toledo, June 1 to 3, Dr. Charles Lukens, Toledo, president-elect, was installed as president, and the following officers were elected: president-elect, Dr. Wells Teachnor, Columbus; president emeritus for one year, Dr. John C. Reeve, Dayton, the oldest member of the association (this position is honorary and is granted in recognition of unusually distinguished ability or service). Columbus was selected as the next place of meeting.

New Sanitary Code.—The Ohio Sanitary Code was submitted to the public health council of the state department of health for approval, May 14, and this code will become effective July 1, 1920, on which date all rules and regulations formerly adopted by the state board of health or public health council are repealed. The new code consists of regulations regarding the reporting of communicable disease, naming the ailment according to its classification as a dangerous disease and stating who is responsible for the report. It includes provisions for notification of such diseases as are found in institutions and for the reporting of deaths from notifiable diseases to the state board of health. It embodies the necessary measures for the prevention and control of communicable diseases, including quarantine, isolation and disinfection. Provisions are also included for the transportation of the dead, and for the inspection and examination of school teachers, janitors and children. Essential rules have been drawn up for the operation of tuberculosis and maternity hospitals, including provisions for the record of the patients, advice as to equipment and medical supervision, and regulations as to examination and treatment.

The new code also has a section dealing with the maintenance of sanitary control of the state park sanitary district, the construction of sewage disposal plants, removal of garbage and the protection of food from flies and dust.

OREGON

Alumni Meeting.—The eighth annual meeting of the Alumni Association of the Medical School of the University of Oregon was held in Portland, May 31 to June 2. This was known as the MacKenzie Memorial meeting, and the program consisted of clinics at five hospitals and the reading of papers at the afternoon sessions. Dr. Ludvig Hektoen, Chicago, delivered the Noble Wiley Jones lectures under the auspices of the medical school on Monday and Wednesday evenings, on the subjects, "Phases of Streptococcic Infection," and "Old and New Knowledge of Immunity." On Tuesday, the annual banquet and business meeting was held, and the following officers were elected: president, Dr. Otis F. Akin, '09, Portland; vice presidents, Dr. George A. Cathey, '09, Portland; Carl J. Hoffman, '02, Woodland, Wash.; Charles L. Rybke, '09, Portland, and Christian E. Stafrin, '11, Portland; secretary, Dr. Adalbert G. Bettman, '07, Portland, and treasurer, Dr. Kitty Plummer Gray, '00, Portland.

PENNSYLVANIA

Ambulance Men Meet.—More than 500 registered for the first U. S. A. A. C. reunion of soldiers of the United States Ambulance Corps, gathered at Camp Crane on the Allentown fair grounds, June 8.

Physicians' Golf Club Organized.—The Aesculapius Golf Club has been organized at Pittsburgh with Dr. Lee V. L. Brown, Castle Shannon, president; Dr. Jesse S. Demuth, Pittsburgh, vice president, and Dr. Edward J. McCague, Pittsburgh, secretary-treasurer.

Death of Noted Chemist.—Dr. Leonard Merritt Liddle, aged 36; senior industrial fellow of the Mellon Institute of Research, Pittsburgh, since 1912, and from 1914 to 1916 head of the biochemistry department of the University of Pittsburgh School of Medicine; president of the Robert Kennedy Duncan Club; a chemist of marked ability in research; died, February 21.

Philadelphia

Physical Directors Visit Colleges.—Members of the Middle Atlantic Physical Directors' Society, in session in Philadelphia, visited Jefferson and Hahnemann medical school, June 11, and heard lectures on medical problems relating to physical education.

Personal.—Dr. Miriam Warner has been appointed physician in the bureau of charities and corrections by Director Ernest L. Tustin of the department of public welfare, and will have charge of treatment of all women at the Home for the Indigent at Holmesburg and the House of Correction. —Dr. John E. B. Buckenham, superintendent of the City Hospital for Contagious Diseases since 1914, has resigned to become librarian of the Masonic Grand Lodge of Pennsylvania.

CANADA

Doctors Increase Fees.—Hamilton, Ont., physicians are the latest to increase their fees. Hereafter daily calls will be \$3; emergency calls and night calls after 6 p. m., \$5; office visits, \$1.50, and obstetric cases, \$25.

Measles and Smallpox in Ontario.—The epidemic of measles in Ontario is growing. From a total of 3,768 cases of communicable diseases reported during May, the cases of measles numbered 2,264 with forty-five deaths. Two hundred and ninety cases of smallpox were reported with no deaths.

Director-General Resigns.—Major-Gen. John Taylor Fotheringham, C. M. G., who has for the past few years been director-general of Canadian Military Medical Services, with distinguished service overseas, has resigned and has left Ottawa to take up practice in his old home in Toronto.

Dominion Association Meeting.—The fifty-first annual meeting of the Canadian Medical Association will be held in Vancouver, B. C., June 22 to 25, under the presidency of Dr. Robert E. McKechnie, Vancouver. The address in medicine will be delivered by Dr. Charles Lyman Greene, St. Paul, Minn., on "Certain Fundamental Errors in the Diagnosis of Myocardial Insufficiency"; that in surgery, by Dr. Edward W. Archibald, Montreal, on "The Surgical Treatment of Ulcerated Intestinal Tuberculosis, as Occurring Chiefly in the Course of Pulmonary Tuberculosis"; that in orthopedics, by Dr. Virgil

P. Gibney, New York City, on "Development and Scope of Orthopedic Surgery," and that in public health, by Dr. John Amyot, Ottawa, Ont., on "The Federal Government and Public Health." Symposiums will also be held on goiter, pulmonary abscess and the stomach and duodenum.

GENERAL

New Officers for Examining Board Federation.—At the annual meeting of the New England Federation of Medical Examiners held in Boston, June 1, Dr. Charles Duncan, Concord, N. H., was elected president; Dr. Michael F. Fallon, Worcester, Mass., vice president, and Dr. Samuel H. Calderwood, Boston, secretary.

Roentgenologists to Meet.—The American Roentgen-Ray Society will hold its twenty-first annual meeting in Rochester and Minneapolis, Minn., September 14 to 17, under the presidency of Dr. James T. Case, Battle Creek, Mich. The sessions of the first day of the meeting will be in Rochester and of the following three days in Minneapolis.

International Sanitary Conference.—At a recent meeting of the committee on arrangements for the Sixth International Sanitary Conference to be held in Montevideo, Uruguay, December 12 to 20, plans for the conference were formulated, and it was recommended that invitations be extended to all the countries of North and South America to assist in the conference.

Medico-Psychologists Hold Meeting.—At the annual meeting of the American Medico-Psychologic Association held in Cleveland, June 1 to 4, Boston was decided on as the next place of meeting, and the following officers were elected: president, Dr. Owen Copp, Philadelphia; vice president, Dr. Sanger Brown, Chicago, and treasurer, Dr. Harry W. Mitchell, Warren, Pa.

General Gorgas Abandons Trip.—Major-Gen. William C. Gorgas has been obliged to abandon his mission to West Africa where he was to investigate sanitary conditions under the auspices of the Rockefeller Foundation. General Gorgas recently suffered a cerebral hemorrhage, complications developed and his condition remains serious. He will probably return to the United States as soon as he is able to travel.

Disposal of Army Medical and Hospital Supplies.—The surplus property division of the office of the Quartermaster General at Washington is offering for sale large quantities of various medical and hospital supplies. A list of these supplies was published on advertising pages 38 and 39 of THE JOURNAL for April 24, 1920. Lists of articles that are still unsold are being furnished on application to Director of Sales, Munitions Building, Washington, D. C.

Rockefeller Gifts to Medical Work.—The General Education Board of the Rockefeller Institute announces a gift of \$5,000,000 to the Rochester University to be used in conjunction with a second \$5,000,000 donated by George Eastman for the founding of a school of medicine and dentistry. A second gift of £1,250,000, with additional smaller sums, is to be given the London University College and Hospital School for a building program whereby the facilities of the college are to be extensively improved for the training of personnel and the setting of standards for health work throughout the British Empire.

Venereal Disease Survey.—Surgeon-General H. S. Cumming, U. S. Public Health Service, announces that approximately 465 of the larger cities of the United States have been surveyed to determine the measures in force for combating venereal diseases. These data are to be published shortly. In four or five months another study of the same localities will be made and the results published. In order that this public health problem may be successfully handled, the cooperation and support of the members of the American Medical Association, its constituent state associations and their component county societies is solicited. The Surgeon-General is desirous of having the support both of these correlated organizations and the influence of their members as leaders in lay organizations—churches, Y. M. C. A., Y. W. C. A., fraternal bodies, rotary clubs, women's clubs and similar societies.

Republican Health Plank.—The following plank on education and health was adopted by the Republican National Convention:

We endorse the principle of federal aid to the states for the purposes of vocational and agricultural training.

Wherever federal money is devoted to education, such education must be so directed as to awaken in the youth the spirit of America and a sense of patriotic duty to the United States.

A thorough system of physical education for all children up to the age of 19, including adequate health supervision and instruction, would remedy conditions revealed by the draft and would add to the economic and industrial strength of the nation. National leadership and stimulation will be necessary to induce the states to adopt a wise system of physical training.

The public health activities of the federal government are scattered through numerous departments and bureaus, resulting in inefficiency, duplication, and extravagance. We advocate a greater centralization of the federal functions, and in addition urge the better coordination of the work of the federal, state, and local health agencies.

LATIN AMERICA

Yellow Fever in Brazil.—Our Brazilian exchanges mention that several cases of yellow fever have been reported recently at Bahia, and several deaths have occurred at different points in the Alagóas region to the northeast.

Plague in Mexico.—According to the last reports, two new cases and three suspected cases of plague have been reported at Vera Cruz, and two deaths among those previously stricken. Two cases were also reported at Tampico.

Personal.—Dr. A. Neiva, chief of the public health service of the state of S. Paulo, Brazil, has been commissioned by the authorities to study the organization of the public health service in Japan and the United States, and the prophylaxis of leprosy in Norway, the Philippines and Hawaii.

Society Election.—The Sociedad de Cirujía of Buenos Aires recently elected as president, Dr. D. J. Cranwell; vice president, Dr. E. Beláustegui; treasurer, Dr. M. Viñas; secretary, Dr. R. Pasman; director of the *Revista*, Dr. D. A. Ceballos, and other directors Dr. P. Chutro and Dr. D. F. Prando.

Election of Officers.—The officers elected for the 1920-1922 term of the Asociación Médica Argentina are Dr. P. Escudero, president; Dr. J. S. Passeron, vice president; Dr. C. Domínguez, secretary general; Dr. J. Iribarne, director of the council on publications; Dr. E. Fidanza, treasurer, and Dr. R. A. Rivarola, librarian.

New Military Hospital at S. Paulo.—The corner stone of the new military hospital was laid in 1918 and it was recently inaugurated with much ceremony by state and military authorities. It was completed in eighteen months at an expense of about \$369,000. Major Affonso Ferreira is to be the director of the new hospital.

FOREIGN

New Dermatologic Journal.—With the name *Acta dermatovenerologica* a new journal has been founded by physicians in the Scandinavian countries, to be published in the three main European languages as material accumulates. The editor-in-chief is Professor Almkvist, Sjukhuset St. Gården, Stockholm. Each volume is to include about 500 pages, and the subscription to the volume is 20 Swedish crowns.

Health Survey of Haiti.—Dr. John Swan, who was recently sent to the Dominican Republic and Haiti by the American Red Cross to make a survey of sanitary and health conditions, reports an urgent need for help, especially as regards modern medical treatment and sanitary housing. In his opinion, immediate steps should be taken to fight venereal disease, hookworm, malaria, and yaws, to establish antituberculosis measures and to teach personal hygiene.

Vital Statistics of Portugal.—According to figures published in the *Medicina contemporanea* the average rates for the years 1913 to 1917 per thousand inhabitants of Portugal and the Azores and Madeira islands were 6.10 marriages, 31.13 births and 20.13 deaths. The figures for Lisbon alone are 7.25 marriages, 24.29 births and 21.91 deaths. The death rate in the home country has increased during the five years from 20.52 to 21.50. The losses by emigration averaged 5.30. The population of Portugal in 1911 was 5,957,985.

Medical History of the World War.—Portugal was among the first nations to send a civilian medical unit to the front. Dr. Reynaldo dos Santos of Lisbon organized the unit and was in charge of it in France, long before Portugal entered the war. The profession in Portugal is now collecting data to compile the medical history of the war. To inaugurate this task, the *Medicina contemporanea* is publishing a list of the titles and a bibliography of articles that have appeared in Portuguese journals, society transactions or elsewhere, bearing on the war.

The Parkin Prize.—In the terms of a bequest made to the Royal College of Surgeons, Edinburgh, by the late Dr. John Parkin, a fellow of the college, a prize is offered for the best essay on "The Curative Effects of Carbonic Acid or Other Forms of Carbon in Cholera, for Different Forms of Fever and Other Diseases." The prize is 100 pounds sterling. The contest is open to competitors of all nations. Essays intended for competition must be written in the English language, must bear a motto and be accompanied by a sealed envelope bearing the motto outside and the name of the author inside, and must be received by Dr. J. S. Fowler, secretary of the college, not later than December 31.

Deaths in Other Countries

Dr. A. Suazo of Comayagua, Honduras.—Dr. J. J. Naón of Tucuman, Argentina, professor of anatomy at the university of Buenos Aires until his resignation in 1906.—Dr. F. T. Christen, a well known roentgenologist of Lausanne, was drowned recently.—Dr. Karl Toldt, professor emeritus of anatomy at the University of Vienna, aged 80.

CORRECTION

Pathological and Not Bacteriological.—In THE JOURNAL of May 1, an Alabama item stated erroneously that the Birmingham Bacteriological Society was formed on March 17 with fourteen members. The society referred to is the Birmingham Pathological Society which was organized on that day, with thirty members.

Error in Discussion of Syphilis.—Dr. G. E. Humphrey, Cambridge Springs, Pa., calls attention to the fact that in the discussion of a paper by Dr. Sanger Brown on "Syphilis," THE JOURNAL, June 5, page 1569, Dr. S. W. Lindsay of Topeka, Kan., says: "Twenty years ago I treated a young man who had syphilis, with the old time salvarsan." Dr. Humphrey calls attention to the fact that salvarsan was not introduced until about 1910.

Government Services

Army Medical School Graduation

The commencement exercises of the Army Medical School were held May 28, in the new National Museum Auditorium, Washington, D. C., Major-Gen. Merritte W. Ireland, Surgeon-General, U. S. Army, presiding. Newton D. Baker, Secretary of War, addressed the graduates and presented the diplomas. The Hoff Memorial Medal was awarded to Major Seymour C. Schwartz, M. C., U. S. Army, and was presented by Major-Gen. Merritte W. Ireland; the Sternberg Medal was awarded to Lieut. August Pacini, M. C., U. S. Army, and was presented by Col. Richard Sternberg, and the Skinner Medal was awarded to William O. Callaway, and was presented by Major John O. Skinner, M. C., U. S. Army, retired. A class of twenty-seven was graduated.

Health Conditions of the Army

Health conditions among troops in the United States continue excellent as evidenced by the decrease in the admission and noneffective rates. There were three new cases of pneumonia reported during the week from Camp Taylor, which for the last few weeks has been reporting a number of sporadic cases of measles. The number of admissions for influenza and measles show a slight increase over last week. There were fifteen new cases of influenza reported during the weeks all from the Eastern Department. The death rate for disease, 4.0, is considerably higher than last week, 2.7. Of thirteen deaths from disease reported, tuberculosis was given as the cause in four, pneumonia and scarlet fever, one each, and streptococcic meningitis three.

Our Present Knowledge of Immunity

Since 1901, when Metchnikoff published his classic work on immunity, our knowledge of the phenomena of immunity has been considerably augmented, especially in the domain of serology. It is no exaggeration to state that the study of these phenomena has been raised to the status of a distinct and independent science. Unfortunately, up to the present, the fundamental literature of this new science is scattered in the special periodicals. We are in need of a general statement of the laws of immunity. No one was better qualified to make such a statement than Prof. Jules Bordet, director of the Pasteur Institute of Brussels. The works of Bordet have, in fact, played an important rôle in the progress of immunology, for it is only since 1898, with Bordet's discovery of hemolytic serums, that the question of the resistance of the organism to pathogenic agents has been able to assume an important position. Bordet's "Traité de l'immunité dans les maladies infectieuses" (just published by Masson et Cie, Paris) undoubtedly represents the most complete exposition of the problem of immunity which has yet appeared. It deserves being called to the special attention of the American medical profession, for the study of immunity has always created a lively interest in the United States. The organization of the American Association of Immunologists in itself sets a good example to the Old World.

Indications for Heliotherapy

At the congress for the promotion of mineral water, climatic, bathing and mountain health resorts, recently held at Monaco, Dr. d'Oelsnitz of Nice made an interesting report on heliotherapy as an auxiliary to climatic treatment.

In surgical tuberculosis marine heliotherapy is apparently the agent of choice. But mountain resorts should not be ignored. Less stimulating than the northern sea coast, they are still the preferable indication for certain nervous and excitable patients. Tracheobronchial tuberculosis is clearly admitted in the list of diseases amenable to treatment by sunlight. In pulmonary tuberculosis, on the other hand, despite early enthusiasm, there is a growing tendency away from this measure. Sunlight can be applied with advantage in pleural tuberculosis after disappearance of the effusion. In pulmonary tuberculosis, heliotherapy often exerts a prophylactic action by arresting the development of glandular foci. For injuries, and atonic and infected wounds, heliotherapy should be employed no matter where. This is not true of disorders of general nutrition, digestive and nervous affections; these are amenable to heliotherapy only secondarily or accidentally, and climatic treatment is always the primary indication. An exception should be noted in rickets, in which heliotherapy at the seaside is the elective treatment. In his conclusions, Dr. d'Oelsnitz insisted on the necessity of subordinating, by attentive observation of the individual reactions, the intensity of treatment to the local and general effects produced in a given case. In a word, the indications for, and the dosage and technic of heliotherapy, aside from a few approximate rules, must still be based more on the individual patient than on climatic factors.

The congress, agreeing with these conclusions, resolved that because of possible accidents and complications, heliotherapy should always be subjected to medical supervision.

Antituberculosis Campaign of Red Cross Societies

The last number of the *Bulletin de la Comité National de defense contre la tuberculose* is exclusively devoted to the antituberculosis work of Red Cross societies during and after the war. Besides giving space to the activities of each of three French Red Cross societies (Société de secours aux blessés militaires, Union des Femmes de France, and Association des Dames françaises), the *Bulletin* gives prominence to an article by Professor Letulle on the rôle of the American Red Cross in the campaign against tuberculosis in France during the war.

LONDON

(From Our Regular Correspondent)

May 29, 1920.

A Systematized Medical Service: A Revolutionary Scheme

A scheme which will revolutionize medical practice in this country and is certain to be adopted, whether in a modified form or not, has been officially brought forward. It is even more revolutionary than the national insurance act, which simply extended contract practice from a section of the working classes to the whole, making provision for illness compulsory instead of optional, and subsidizing the system. The new scheme affects the whole of medical practice and aims at bringing within the reach of every patient all the advances of science and the expensive and complicated equipment necessary for their application.

When the ministry of health was formed last year, provision was made for a consultative council, consisting of physicians, to advise the minister on medical affairs. He invited it to consider the problem of a systematized medical service. The council has now presented its report, which begins with a description of the failure of the present organization of medicine to bring the advantages of medical science within reach of the people. Medical treatment, while becoming more effective, tends to become more complex. This tendency is exemplified in the modern handling of such complaints as appendicitis and tuberculosis. As the complexity of treatment becomes greater, it grows increasingly difficult for the individual practitioner to administer the full range of treatment, requiring, as it does, access to such resources as those of bacteriology, biochemistry, radiology and electrotherapeutics, while the number of patients who can afford to pay for it diminishes. Public opinion, again, appreciates more and more that the home does not always afford the best hygienic conditions for recovery from serious illness. Any scheme of medical service must be open, though not necessarily free, to all classes of the community; it must be such as can grow and expand and adapt itself to varying local conditions, and in each locality it must comprise and provide for all the medical services, preventive and curative, necessary to the health of the people, all these agencies being brought together in close coordination under a single health authority for each area.

At the center of the medical service of the country lies the treatment which the physician gives to his patient, either at his own office or at the patient's house. This domiciliary medical service should continue, the physician attending his patients as heretofore, either at their own homes or at his office, and carrying out there such treatment as falls within his competence. All domiciliary service would, however, be brought into relation with a "primary health center" which would serve as the rallying point of all the medical services, preventive and curative, of the district.

There would be, at the primary health center, wards of varying sizes and for varying purposes, including provision for midwifery, an operating room, a roentgenography room, a laboratory for simple investigations, a dispensary, medical

baths, and a common room which would serve as a meeting place for the physicians of the district and for the storage of clinical records on an agreed and standardized basis. There would also be accommodation for communal and preventive services, such as those for prenatal care, child welfare, medical inspection and treatment of schoolchildren, physical culture, and the examination of suspected cases of tuberculosis. So far as midwives and nurses are not available in particular districts under other arrangements, their services could be provided from a center. A dental clinic with a staff of visiting dental surgeons would be another important branch of the equipment.

These primary health centers, one of which should ultimately be found in every convenient center of population, should be staffed by the physicians of the district, patients who visited them or were accommodated in them retaining the services of their own physician. The physician would be able to arrange for the transference of a patient to the primary health center where, retaining the patient still under his own care and control, he would be able to continue the treatment under more favorable circumstances and with a readier access to the resources of modern medical science than are afforded in the office or are possible within the patient's own home. The primary health center would provide the patient (on the terms described below) with food, nursing and all equipment for efficient treatment, but not with medical attendance, which would be paid for either by the patient himself (if a private patient) or through some method of insurance or by the local health authority. While the primary health center thus provided the physician with means not now generally available of offering his patient what may be described as "hospital treatment," while still keeping him under his own control, it would also serve the physician, as a center of professional life, bringing him into daily contact with the other physicians of his district, and occasional contact with the consultants and specialists who would attend at fixed intervals from the "secondary health centers" with which each group of primary centers would be brought into relation.

The "secondary health centers" would be situated in a town where an adequate equipment would be possible and an efficient staff of consultants and specialists could be assembled. Each secondary health center would be within access of all the primary health centers in the area. For many secondary centers the nucleus of organization would be found in existing hospitals. Like the primary health centers, the secondary centers would bring together into one organization agencies both of preventive and curative medicine, though in the secondary center each agency would be of a more specialized character. On the curative side, for example, the services of the secondary health centers would be mainly of a consultative type. They would receive cases referred to them by the primary centers either on account of difficulties in diagnosis or because in the diagnosis or treatment of such cases a highly specialized equipment was necessary. Secondary health centers would, in fact, need a complete hospital equipment.

Patients referred for consultation or treatment from the primary health centers would attend at the outpatient clinics of the secondary center or would occupy inpatient beds. The medical staff of the secondary center would be responsible for the treatment of these patients, but physicians would have every opportunity to keep in touch with their patients while attending the center and to resume supervision over them on discharge. The duties of consultants attached to secondary centers would consist of regular attendance at fixed times in their outpatient clinics where they would see cases referred to them; periodic visits to primary health centers in the district allotted to them, and special visits of

emergency to primary health centers and, in certain circumstances, to the homes within their areas, always in consultation with the physician. The consultants would be part-time officers and would be paid on a time basis, with extra fees for special visits. Where it is geographically possible, every secondary health center should be brought into relationship with the teaching hospital. The teaching hospital of the district would be found in some large city, and to it would go cases of unusual difficulty from secondary and primary health centers, which would in turn be permeated by the academic influence and the spirit of inquiry and progress associated with a teaching hospital. While preventive services must of necessity be publicly provided, the provision of curative services free of charge at the health centers would impose a heavy burden on public funds. In the public wards of the primary and secondary health centers, standard charges should be made for treatment, though these charges might vary in different parts of the country, and they could only as a rule be a contribution to the cost of treatment, which is often in its entirety beyond the means of many citizens. Private and self-supporting wards should be a part of the provision at the health centers, though the essential services in the public and private wards would be identical.

In order to administer the scheme in each district, the council glances at the need for a new type of local health authority to bring about unity of local control of all health services, curative and preventive. On this body the council asks for due representation of the medical profession, and is of opinion that the authority should in each case be assisted by a local medical advisory council.

On the subject of a state medical service, it says: "The alternative of a whole-time salaried service for all doctors has received our careful consideration, and the council holds that by its adoption the public would be serious losers. No doubt laboratory workers and medical administrators who do not come in personal contact with the sick can with advantage be paid entirely by salary. The clinical worker, however, requires knowledge not only of the disease but of the patient: his work is more individual, and if he is to win the confidence so vital to the treatment of illness, there must be a basis not only of sound knowledge but of personal harmony. The voluntary character of the association between doctor and patient stimulates in the former the desire to excel both in skill and helpfulness. In no calling is there such a gap between perfunctory routine and the best endeavor, and the latter would not be obtained under a whole-time state salaried service, which would tend, by its machinery, to discourage initiative, to diminish the sense of responsibility, and to encourage mediocrity."

VIENNA

(From Our Regular Correspondent)

May 28, 1920.

Work of the American Red Cross

In April, the American Red Cross took up its welcome work in Vienna, and its beneficial effects are now felt in all hospitals and charitable institutions. The chief aim of the work is to assist the hospitals and convalescent homes in their special efforts, by distribution of the necessary articles of food and nursing supplies. A committee of Vienna physicians is cooperating with the Red Cross in this respect. Infants and nursing mothers are receiving special attention by distributions through the Society of Friends, which depends chiefly on the resources of the Red Cross for its humanitarian work. A large number of charitable institutions which direct their attention to the deplorable conditions of the so-called middle classes (the latter are now really worse off), receive valuable gifts in the form of food

and clothing. It is a good idea that articles of clothing, garments, linens, bed-clothes, etc., show a small label, bearing the words "Compliments, American Red Cross," with the name of the district and the town whence they are sent. Major Davis, in charge of the Department of Vienna, lays special stress on the fact that the American officers connected with the Red Cross do not interfere with commercial, political or religious affairs of the communities in which they are working. Among the most valuable articles provided by the American Red Cross are medicines and drugs which are not obtainable here. Quinin, opium, morphin, cocain and camphor are real rarities. The price for morphin, for instance, rose to 800,000 Kroner (over \$4,000) per kilogram. Surgical instruments and objects made chiefly of glass or rubber, which are needed very badly, are available at the Red Cross storehouses in great quantities; the same is true of clothing for hospital patients, shirts, gowns, robes, shoes and the like. Furthermore, 4,000 cases of emergency rations of the American Army, including cocoa, condensed milk, preserved meat, salt, sugar, tea and matches are in storage awaiting distribution. The funds and stocks of the organization are being constantly replenished, so that the activities appear to have a permanent character. This work will prove not only a most valuable help in distress, but it will impress the public with the earnestness and the humane feelings of the American people as a whole.

Dearth of Foreign Scientific Literature

As has been pointed out previously, the scientific institutes of Vienna are very much handicapped in their work by the deplorable lack of books and periodicals published abroad since the outbreak of the war. Because of the exchange rates, the institutions with their insignificant funds cannot purchase foreign journals or books, since, for instance, the annual subscription of a single leading American, English or French medical periodical consumes from 20 to 25 per cent. of the total sum available. Appeals for gifts of periodicals have been made by the University of Vienna to different foreign institutes, but to date the results are very meager. Another subject of distressing nature is the constant rise in the cost of printing and of paper, whereby the medical press of the country is seriously hampered, with the imminent danger that some of our most distinguished medical periodicals will be forced to suspend publication. Naturally, not only the students in the institutes are materially interested in the matter, but also the general practitioners. It is difficult to see how they are going to keep abreast with the scientific work of the world, and how they will succeed in publishing the results of their own investigations, if the chief means of international communication are suppressed.

The Campaign Against Prostitution and Venereal Diseases

From time to time the daily papers publish items about the fight being waged by the police sanitation committee on prostitution. However, the problem is surrounded by so many difficulties, that public discussion of this serious matter is not readily countenanced. The facts underlying the problem are as follows: It is clearly understood that the great war caused an enormous increase in the incidence of venereal diseases, while the morals of the general public have been quite lax. In all large cities of the continent, public and clandestine prostitution has been promoted to a most deplorable degree by the accumulation of soldiers, but perhaps nowhere so much as in Vienna. Here had economic conditions have contributed with other factors to deprave the moral standard of certain classes of women. In former times the "street-walker" or the occasional clandestine prostitute hailed chiefly from such classes as waiters, unemployed

housemaids and factory girls, while today, these form only a small percentage of the grand total. Now shop girls, clerks, typewriters, and even daughters and wives from reputable families become victims of the economic misery. Not so much the desire for luxury and pleasure as sheer poverty and hunger drive them to the road of shame. The figures obtained by the police are simply appalling. The police, as a routine matter, make surprise visits to small hotels, hostelries, bars and similar places, and cause all women found there without good reasons to be examined. In 1919, 7,000 women and girls were arrested under suspicion of clandestine prostitution. Of these over 1,700 suffered from manifest venereal disease, and 2,400 were dealt with by a special department of the police. Among the latter, 800 were between 18 and 21 years of age, more than 40 per cent. being venereally infected. An additional 380 were under 18 years of age, and of these 50 per cent. were diseased. Even worse conditions were found in the "surprise raids" conducted this year. Up to April 1, the police department had ordered the examination of over 800 women and girls found in suspicious surroundings. Ninety girls were between 14 and 18 years old, 60 per cent. of them diseased, and nearly 40 per cent. of all those examined were found infected. Naturally this represents only a percentage of those who actually lead such a life. The counterpart is to be found in the outpatient departments of our dermatologic clinics, where the number of men suffering from venereal diseases is constantly increasing. The government has instituted a number of so-called evening ambulatory clinics in all districts of the city, chiefly on the outskirts where the working classes are congregated. Altogether about twenty-five such ambulatory clinics are now functioning, conducted by duly qualified specialists in venereal diseases. Here, investigations are being made as to the source of infection, and it appears that about 70 per cent. of all men cohabiting with prostitutes become infected in spite of all prohibitive and prophylactic measures. Therefore the police have recommended the adoption of a law enforcing the examination, and, where necessary, the detention and treatment of the male partner in all instances of prostitution. For what does it avail to detain the women while the men are permitted to disseminate venereal diseases ad libitum? The idea has been commented on favorably by medical experts and by the government, and in the new health act, now under consideration, this point will be earnestly dealt with. It is proposed to make the wilful transmission of venereal diseases, irrespective of the sex of the culprit, a punishable offense and to enforce compulsory treatment of venereal diseases.

Marriages

CLARENCE J. MANLY, Colonel, M. C., U. S. Army, to Mrs. Mabel Graham Billingslea of Westminster, Md., at Baltimore, June 5.

WILLIAM PARKER HERBST, Rochester, Minn., to Miss Catherine Arnold of Chicago, at Lake City, Minn., June 12.

JULIUS ASHER MILLER, New York City, to Miss Pearle M. Lebowich of Dixon, Ill., May 28.

LEWIS SAMUEL BOOTH to Miss Elizabeth Willard Stead, both of New York City, June 1.

STEWART ELLSWORTH MANDEVILLE to Miss Fern Anderson, both of New York City, May 4.

LEE HOLLISTER FERGUSON to Miss Margaret A. Knapp, both of New York City, May 20.

EDWARD T. JUCHHOFF, Chicago, to Mrs. Lois E. Masters of Jacksonville, Ill., April 22.

MAX JOHN SCHROEDER to Miss Shirley Goldberg, both of New York City, June 12.

Deaths

Joseph Willis Houston, Lancaster, Pa.; Jefferson Medical College, 1857; aged 86; a member of the Medical Society of the State of Pennsylvania, assistant surgeon of Pennsylvania Volunteers during the Civil War; professor of natural sciences at Lincoln University for six years, and dean of the faculty of the medical department; surgeon of the Maryland Division of the Pennsylvania system for fifteen years; died, June 5.

Edward Herman Miller Sell, New York; Bellevue Hospital Medical College, 1866; aged 87; one of the seven organizers of the New York Academy of Medicine, and the sole survivor; editor of the *Physician and Pharmacist* from 1869 to 1880; a fellow and once vice president and treasurer of the American Academy of Medicine, who made special studies regarding liquor and drug addiction; died, June 6.

Alfred Harris Kelly, Louisville, Ky.; Louisville, Ky., Medical College 1895; aged 46; Captain, M. C., U. S. Army, and discharged on account of physical disability August 21, 1918; formerly coroner of Jefferson County, and professor of chemistry and toxicology at the University of Louisville; for more than a year medical director of Hazelwood Sanatorium; died, May 28, from cerebral hemorrhage.

Carl John Ringnell * Minneapolis; University of Minnesota, Minneapolis, 1891; aged 55; a member and executive secretary of the State Board of Medical Examiners and a leader of the movement which resulted in the enactment of an anti fee-splitting law; one of the founders of the Swedish Hospital, Minneapolis; at one time deputy coroner of the city; died, June 2.

Henry James Millard, North Adams, Mass.; Berkshire Medical College, Pittsfield, Mass., 1864; aged 84; a member of the Massachusetts Medical Society; a member of the staff of the North Adams City Hospital; assistant surgeon of the Thirty-Fourth Massachusetts Volunteer Infantry during the Civil War; died, May 30, from heart disease.

James Sylvanus Sprague, Belleville, Ont.; Victoria University, Cobourg, Ont., 1869; Trinity Medical College, Toronto, 1890; aged 75; for several years examiner on materia medica and therapeutics of the Medical Council of Ontario, and once a member of the State Board of Medical Examiners of Iowa; died, April 23.

Isaac A. Shirley, Winchester, Ky.; University of Louisville, Ky., 1875; Bellevue Hospital Medical College, 1879; aged 71; a member and president in 1909 of the Kentucky State Medical Association; formerly vice president and president of the Clarke County Medical Society; a member of the State Board of Health; died, June 5.

Edward Dennis McGiverin, Jersey City, N. J.; University and Bellevue Hospital Medical College, 1909; aged 34; Lieutenant, M. C., U. S. Army, during the World War, and resigned on account of poor health; while on his way to California for his health, died at the Elk's Club, Salt Lake City, June 7.

William S. Jones * Camden, N. J.; Jefferson Medical College, 1878; aged 62; for fourteen years a member of the faculty of his alma mater; superintendent of the Old Soldiers Home, Vineland, N. J., and State Medical Examiner of Institutions; died, June 8, from heart disease.

John Harrell Maxwell, Newton, Ill.; Medical College of Ohio, Cincinnati, 1878; aged 85; hospital steward of the Thirty-Eighth Illinois Volunteer Infantry during the Civil War; one of the founders of the Jasper County Medical Society; died, April 3, from cerebral hemorrhage.

Antonio Villanencio, Taal, Batangas, P. I.; Santo Tomas University, Manila, P. I., 1915; a member of the Philippine Islands Medical Society, who was taking a postgraduate course in New York; died in the Post-Graduate Hospital, New York, February 6, from lobar pneumonia.

Burl Samuel Hood, Bond, Miss.; University of Nashville, 1906; aged 39; a member of the Mississippi State Medical Association; lieutenant, M. C., U. S. Army, with service in France, and discharged July 3, 1919; was shot and instantly killed at the home of a patient, June 3.

Ferdinand Siegel * Brooklyn; University of the City of New York, 1890; aged 53; chief of the general medical staff and associate pediatrician in Bedford Maternity Hospital; died, May 25, from a nervous breakdown.

Francis Joseph Adams * Great Falls, Mont.; Georgetown University, Washington, D. C., 1881; aged 60; a specialist in surgery; while returning in his automobile from Belt to Great Falls, Mont., June 2, was killed by the overturning of his car.

Harry Dushane Todd * Akron, Ohio; Eclectic Medical Institute, Cincinnati, 1898; aged 43; police surgeon of Akron for fifteen years; visiting physician to the Akron City Hospital; died, May 25, from heart disease.

Richard William Muller * New York; University of the City of New York, 1879; aged 69; a specialist in dermatology; a member of the New York Academy of Medicine; died, June 3, from heart disease.

Nathaniel F. Lindsay, Robinson, Ill.; University of Louisville, Ky., 1878; aged 70; a member of the Illinois State Medical Society; died, March 26, from carcinoma of the pancreas.

William Henry Woodbury, Buffalo; University of Buffalo, 1888; aged 56; a member of the Medical Society of the State of New York; a specialist in diseases of the lungs; died, May 8.

Kesey Shindle Marlin, Dakota, Ill.; Pennsylvania Medical College, Philadelphia, 1854; aged 89; surgeon of U. S. Volunteers during the Civil War; died, March 2, from senile debility.

Alvah M. Davis * Philadelphia; University of Pennsylvania, Philadelphia, 1892; aged 49; assistant to the nose, throat and ear clinic of Germantown Hospital; died, May 14.

Edith Winifred Stewart * Hume, N. Y.; University of Buffalo, 1898; aged 45; died in the Warsaw (N. Y.) Hospital, May 16, three weeks after an operation for appendicitis.

George E. Powell, LaCrosse, Wis.; College of Physicians and Surgeons, Keokuk, Iowa, 1884; aged 71; a noted scout on the plains during the Indian uprisings; died, May 17.

Guy Burrell Stall, Detroit; Detroit Homeopathic College, 1904; aged 39; a member of the Michigan State Medical Society; died, May 17, after an operation for a carbuncle.

Isham Griffin Wilson, Demopolis, Ala.; Tulane University of Louisiana, New Orleans, 1868; aged 76; died at the home of his niece in Selma, Ala., May 17, from heart disease.

William Ardrey Kellogg, Fort Adams, Miss.; Jefferson Medical College, 1897; aged 47; is reported to have been accidentally burned to death in his room, May 17.

Simon D. Shive, Pannerville, Pa.; Baltimore Medical College, 1882; aged 66; a member of the Medical Society of the State of Pennsylvania; died, March 12.

Charles O'Reilly, Toronto, Ont.; McGill University, Montreal, 1867; aged 73; for thirty years superintendent of the Toronto General Hospital; died, May 3.

Wyndon Hewitt Davis, Libertyville, Iowa; University of Iowa, Iowa City, 1920; an intern in Harper Hospital, Detroit; died in that institution, about May 19.

Joseph R. Baker, Sanders, Ky.; University of Louisville, Ky., 1908; aged 43; died in the Jewish Hospital, Louisville, May 11, after a surgical operation.

Harry Abram Cosler, Osborn, Ohio; Ohio Medical University, Columbus, 1902; aged 47; a member of the Ohio State Medical Association; died, May 13.

Clyde H. Duncan, Fairmont, W. Va.; Chicago Homeopathic Medical College, 1894; aged 47; died in the McMillan Sanitarium, Columbus, Ohio, May 12.

Samuel F. Hazlehurst, Colorado Springs, Colo.; University of Pennsylvania, Philadelphia, 1876; died in a hospital in Colorado Springs, May 13.

O. L. Kilborn, Chengtu, China; Queen's University, Kingston, Ont., 1889; a medical missionary for twenty-nine years; died in China, about April 20.

Calvin E. Parker, Los Angeles; Missouri Medical College, St. Louis, 1877; formerly a practitioner of Philo and Champagne, Ill.; died recently.

James Thomas Growdon, Akron, Ohio; Kentucky School of Medicine, Louisville, 1894; aged 52; died, May 9, from the effects of rheumatism.

J. Thompson Hume, St. Petersburg, Fla.; College of Physicians and Surgeons, Baltimore, 1887; aged 64; died, May 15.

William M. Bright, Hickman, Ky.; University of Nashville, Tenn., 1869; aged 73; died, May 11, from heart disease.

Anonymous Earl Hardin * Fort Smith, Ark.; Louisville (Ky.) Medical College, 1875; aged 72; died, May 14.

* Indicates "Fellow" of the American Medical Association.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

FORMITOL TABLETS, II

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following supplementary report on Formitol Tablets.

W. A. PUCKNER, Secretary.

In the Council report (*THE JOURNAL A. M. A.*, Oct. 4, 1919, p. 1077) on the ineffectiveness of lozenges claimed either to contain formaldehyd or to liberate formaldehyd in the mouth, the composition of Formitol Tablets of the E. L. Patch Co. was briefly discussed in the following terms:

"The A. M. A. Chemical Laboratory reported that Formitol Tablets contained formaldehyd (or paraformaldehyd), an ammonium compound, and some hexamethylenamin. It is probable that the formaldehyd (or paraformaldehyd) was produced by the decomposition of hexamethylenamin originally present in the tablets but decomposed by long contact with the acid."

At the time this report was published, the label and the advertising matter contained but vague and indefinite statements with regard to the composition of Formitol tablets. In the October, 1919, issue of *Patchwork*, the house organ of the E. L. Patch Co., it was denied that these tablets contain hexamethylenamin since none had ever been used in their manufacture. It was also claimed that the company had a "printed sheet giving the formula of these tablets."

The Council advised the E. L. Patch Co. that it desires to publish only facts about the products which it examines and that if the report on Formitol Tablets was inaccurate in any way the Council would want to correct any error it might have unintentionally made. As the Formitol advertising in the files of the Council contained no information as to the composition of the tablets, the firm was also requested to send the printed sheet giving the "formula."

When this printed "formula" came it was found to be a sheet used by the E. L. Patch Co. for the purpose of giving its salesmen information regarding Formitol tablets, to be passed on to the physician. This printed sheet conveyed the information that Formitol Tablets contain ammonium chlorid, benzoic acid, citric acid, guaiac, hyoscyamus, menthol, paraformaldehyd and tannic acid, but it gave no information in regard to the amount of any of the ingredients except that it declared that each tablet represents the equivalent of 10 minims of a 1 per cent. formaldehyd solution.

Because of the nonquantitative and therefore meaningless printed "formula" and because, also, of its complexity, it was thought desirable to make a more complete analysis of Formitol Tablets. Experience has shown that frequently the real formula of a thing is quite different from the alleged formula published by the manufacturer. The details of the laboratory's later analysis will appear in the Annual Reports of the Chemical Laboratory or may be had on request.

The result of the laboratory's additional experimental work, especially when taken in connection with investigations made elsewhere on the interaction of formaldehyd and ammonium chlorid justifies the conclusion that Formitol Tablets do contain some hexamethylenamin, even though the amount may be very small. As the E. L. Patch Co. declare that no hexamethylenamin is put into Formitol Tablets the conclusion drawn in the Council's original report to the effect that the formaldehyd probably was formed by the decomposition of hexamethylenamin was evidently an error. The hexamethylenamin present is doubtless produced by the action of the paraformaldehyd on the ammonium chlorid present.

The analysis also showed that more than 78 per cent. of the weight of Formitol Tablets was made up of sugars and about 16.5 per cent. was starch and other material, some of which was talcum or similar material. This means that about 94 per cent. of the total weight of the tablets is sugar and starch none of which are mentioned in the printed "formula." The significance of this is apparent when it is considered that there are eight ingredients listed in the "formula" for which therapeutic effects are claimed. Since a tablet weighs about 13.5 grains, the combined weight of all the claimed active ingredients is less than 1 grain per tablet!

The amount of ammonium chlorid found, as indicated by the total nitrogen, was not more than 1.0 per cent. or about

$\frac{7}{8}$ grain per tablet. The amount of benzoic acid found was 0.34 per cent. or $\frac{1}{3}$ grain per tablet. Yet these two drugs are said to exert their peculiar expectorant action. (The U. S. P. lozenge of ammonium chlorid contains $1\frac{1}{2}$ grains ammonium chlorid or twelve times the amount of this drug in a Formitol tablet.)

The tannic acid contained in the tablets could not be determined with accuracy but it was much less than 1 per cent. (or $\frac{1}{8}$ grain per tablet) yet it is said to add valuable astringent qualities to Formitol Tablets! (The U. S. P. lozenge of tannic acid contains 1 grain of tannic acid.)

The quantity of guaiac (as resin) is but a fraction of 1 per cent. Yet it is said to impart to Formitol tablets

"stimulant resolvent" properties and it is intimated that there is sufficient to be of value in "cases of abscess of the throat and inflammation of the tissues."

The total acidity indicates the presence of about 2 per cent. of citric acid or $\frac{1}{4}$ grain per tablet. Yet this amount is said to be "antiseptic" and "aids in the general results."

While the presence of the drug hyoscyamus (henbane) was not positively identified by microscopic examination, alkaloids were present.

The manufacturers claim that the tablets contain menthol yet only a suggestion of menthol could be obtained from the odor. However the odor of methyl salicylate—a constituent not declared in the "formula"—predominated throughout the operations of analysis.

Formitol tablets furnish a good illustration of some well established but often ignored truths:

1. "Formulas" that are nonquantitative are valueless or worse than valueless.

2. The fact that a manufacturer puts certain drugs in a mixture, is no proof that these drugs are there when the mixture reaches the patient. The physician must be assured that they are there when he prescribes them.

3. Complex mixtures should be avoided. It is absurd to expect, as is claimed in the case of Formitol Tablets, anodyne, antiseptic, astringent, expectorant, and resolvent action all at the same time.

SANATOGEN

SANATOGEN CONSISTS OF 95% CASEIN (DRIED MILK CURD) AND 5% GLYCEROPHOSPHATES. IT IS ADVERTISED UNDER RIDICULOUSLY EXAGGERATED CLAIMS AS A "FOOD-TONIC."

WHAT \$1.00 WILL BUY IN FOOD ENERGY

Sanatogen	
Eggs (54c. dz.)	
Milk (16c. qt.)	
Bread (16c. lb.)	
Sugar (18c. lb.)	
Rice (16c. lb.)	
Beans (10c. lb.)	

There is more food energy in 2 cents worth of Beans (at 10c. lb.) than in One Dollar's worth of Sanatogen.

Miniature reproduction of one of the educational posters prepared by the Propaganda Department of *THE JOURNAL*. The originals measure 22 by 28 inches.

Correspondence

MEASUREMENT OF RADIUM

To the Editor:—In the routine testing of hermetically sealed radium preparations, the ionization produced in a given ionization chamber by the penetrating gamma radiation proceeding from the preparation is compared with that produced under the same conditions by the similar radiation from a standard containing a known amount of radium. Mesothorium preparations also emit a penetrating gamma radiation, and consequently by a single comparison with the radium standard in the manner just indicated there is no means for distinguishing such a preparation from one containing only radium and its derivatives.

It is for this reason that the usual radium certificate issued by the National Bureau of Standards contains no statement concerning the actual amount of radium contained in the preparation, but merely a statement of its equivalent radium content. The primary object of the measurement of such preparations by the bureau is to insure the purchaser against any serious error in the radioactive measurement of the preparation.

The carnotites, from which the domestic radium is produced, are known to contain only a negligible amount of mesothorium. Tests made on radium produced from such ore gave no evidence of the presence of mesothorium, and were such as to indicate that the mesothorium present cannot exceed 0.2 per cent. of the radium content of the material. Consequently, it is quite safe to assume that the radium produced from these deposits will be practically free from mesothorium unless the latter product is deliberately added. This is a matter over which the producer has control and concerning which he can speak with confidence. It is customary for the domestic producers of radium to guarantee that their product is practically free from mesothorium, and such a guarantee might well be requested by the purchaser.

Although the examination of a hermetically sealed radium preparation for the presence of mesothorium forms no part of the routine measurement of such materials by the bureau, such examination will be made when requested under conditions that justify the work. These examinations are laborious, require the opening of the preparation and the removal of some of the salt, and involve the risk of a considerable loss of material. As in the case of all tests made by the bureau, the applicant must furnish the material used, assume the risk of loss, and pay a fee commensurate with the labor involved.

On the other hand, even without this examination the purchaser is not left entirely to the mercy of unscrupulous dealers. Repeated gamma ray comparisons, using radiations filtered through different thicknesses of lead, will in general furnish data from which it can be determined whether much of the radiation from the preparation is due to mesothorium. Such tests on sealed specimens are deliberately made from time to time, and similar but less complete data are incidentally obtained from many specimens in the routine course of the testing. In no case has such test revealed to us the presence of mesothorium in any preparation that has been submitted to this bureau as one free from mesothorium; but few imported preparations have been so tested.

Another check on the possible presence of a significant amount of mesothorium in a radium preparation is afforded by its remeasurement. If the preparation contains a significant amount of mesothorium, then a second measurement made several months after the first will reveal:

1. A growth in the intensity of its radiation if all radiothorium had been removed from the material shortly before the first measurement.

2. Little or no growth if the radiothorium was last removed two or three years before.

3. A decrease of the radiation if the radiothorium had not been removed for over three years.

It is evident that unless the two measurements are very specially related to the age of the contained mesothorium, they will reveal its presence.

In the course of its work, the bureau has to its knowledge remeasured forty-seven radium preparations after intervals varying from two weeks to four years. Preparations from three domestic producers are included in the list. Some of these preparations were resubmitted by their producers, others by their purchasers. For fifteen of the preparations, the interval between these measurements exceeded six months. In no case did the difference between the two measurements exceed the sum of the allowable uncertainties of the two measurements. Excepting a single case in which the initial determination was known to have an unusually low precision, a difference as great as 0.9 per cent. was found in only one instance. The average difference was 0.34 per cent. The second measurement usually, but not always, exceeded the first. This probably results from the fact that in many cases the radium had not fully attained its equilibrium at the time of the first measurement. Even thirty days after the radium preparation is sealed, it is 0.45 per cent. short of its maximum gamma radiation.

Whence it is seen that as yet we have found no indication that any hermetically sealed preparation offered by a domestic producer as a radium preparation contains an appreciable amount of mesothorium. Very few such specimens offered by small dealers, jobbers or importers of radioactive material have been submitted to the bureau. Consequently we are at present not prepared to express an opinion concerning the material obtained from such sources.

S. W. STRATTON, PH.D., Washington, D. C.
Director, Bureau of Standards.

A NEGLECTED AID IN DIAGNOSIS AND PROGNOSIS—THE OPHTHALMOSCOPE

To the Editor:—My object in writing is to promote the more frequent use by the general practitioner of an instrument that is far too little used, considering its value to the medical profession, namely, the ophthalmoscope. The ophthalmoscope is an aid to the diagnosis not only of diseases of the eye itself but also of general diseases. And yet it is deplorable to see what little use is made of this aid by the majority of physicians. In looking over case reports, how often do we see the records of the findings of every test known to science, except the easiest of all tests, the ophthalmoscope? Since easily manipulated electric instruments are now obtainable, a practitioner is lax indeed who does not own one along with his blood pressure apparatus. The most surprising thing of all is that the large insurance companies have not before this insisted on it as part of the examination.

On the other hand, the chief may look at an eye-ground and say nonchalantly to the resident, "There is an interesting case of so-and-so," handing the ophthalmoscope to the resident, who, looking into the eye, does not at once see the condition, but is ashamed to admit it, says that he does, and thereby learns nothing. Thus he goes all through his service, rarely seeing an eye-ground, and later, never even attempting to look at one, as it seems too intricate for him to master. Of course the only solution of this is closer cooperation in the eye department, and the only way in which this can be brought about is for the ophthalmologist to show enough interest in the intern so that he will be glad to learn, and, once having gained the knowledge, will be more likely to follow it up in later years.

By this means the whole interior of the eye is accessible; blood vessels and nerves, which in other parts of the body are exposed only by surgery, are here plainly seen in their normal positions.

From a diagnostic and prognostic standpoint it is the only reliable instrument that we have. By the use of the sphygmomanometer one can tell that the pressure is high at that particular time, but that does not show us whether it is transient or permanent. With the ophthalmoscope, when one finds the small, hard, tortuous or ruptured vessel, one knows definitely that it is a permanent affair, and what the ultimate outlook is. If physicians would use it more generally as a part of the routine examination, many vague and indefinite cases would have their diagnosis established earlier.

L. G. REDDING, M.D., Scranton, Pa.

GAIN IN WEIGHT IN SOLDIERS

To the Editor:—Many exaggerated statements have been made as to the gain in weight soldiers have acquired during the war. So says the Surgeon-General of the Army (*THE JOURNAL*, Feb 21, 1920, p. 499), and he adds that at the present time no correct statement can be made.

The following facts were observed on the personnel of Base Hospital 76, with which we were mobilized at Camp Devens in July, 1918 (first weighing), and with which we served in Vichy, Allier, France (second weighing, six months later). During the first month in the American Expeditionary Forces, 42 per cent. of our unit had so-called influenza, but otherwise suffered comparatively few food difficulties or other hardships, and may therefore be presumed to show as favorable a gain as any command.

Gain in weight was seen in 194 men, or 84 per cent. of the series of the 229 subjects studied; and in these the gain averaged 8 per cent., with a maximum of 25 per cent. above the weight at enlistment. Loss in weight was noted in 10 per cent. of the series and in these the loss averaged 5 per cent. with a maximum of 18 per cent. below the weight at Camp Devens. Constant weight was observed in 6 per cent. of the series, whereas in 94 per cent. there was some change. This variation, averaging gains and losses together, was 7 per cent. of the weight at entry into service. Age played no part, that is, gains were no greater nor more frequent among the younger men than among the older. The foregoing conclusions are derived from figures presented but not analyzed elsewhere (Gray, Horace, and Mayall, J. F.: *Body Weight in 229 Adults*, *Arch. Int. Med.*, to be published).

HORACE GRAY, M.D., Boston, and
F. B. ALLEN, M.D., North Wales, Pa.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

EXAMINATIONS FOR OFFICERS OF MEDICAL DEPARTMENT

To the Editor:—Will it be necessary for a physician who is already in the Medical Reserve Corps to take any further examination in order to enter the regular army? A. A. SIZER, M.D., Schuyler, Va.

ANSWER.—Yes. An examination will be held, July 7, 1920, for officers of the Medical Department at the following places:

Northeastern Department, Headquarters, Boston.
General Hospital No. 6, McPherson, Ga.
General Hospital No. 21, Denver.
General Hospital No. 28, Fort Sheridan, Ill.
General Hospital No. 41, Staten Island, N. Y.
Camp Pike, Little Rock, Ark.
Camp Taylor, Louisville, Ky.

Camp Funston, Manhattan, Kan.
Fort Sam Houston, San Antonio, Texas.
Letterman Hospital, San Francisco.
Walter Reed Hospital, Washington, D. C.

All physicians who served as officers of the Medical Department between April 6, 1917, and June 5, 1920, are eligible, and all grades are open within the restrictions of the law.

Applications must be in the War Department on or before June 23. Applications will be considered only from persons who since March 25 have received and replied affirmatively to inquiry from the War Department as to whether or not they desire further consideration given their application in the Regular Army; also to persons who since March 25 submitted Form 739 to the War Department, and all other eligible persons who submit Form 739 at once. Copies of this form may be obtained through the Surgeon-General's Office.

The age limit for all grades is 58 years: 48 to 58 for Colonel; 45 to 58 for Lieutenant-Colonel; 36 to 58 for Major, with no restrictions regarding captain. Appointment and grade will be determined by record of the applicant while in the service. His rank at the time of discharge will probably not be exceeded in the reappointment. The possession of a medical degree will exempt the applicant from the general educational examination, but a professional examination is required on the subjects of medicine, surgery, sanitation and administration.

FORMULA FOR MOUTHWASH

To the Editor:—Please furnish me with a formula for the best mouth wash to be used by patients after tooth extraction and for general mouth hygiene. I desire this for my private practice and for use in my clinic. A. R. W.

ANSWER.—

LIQUID DENTIFRICE

	Gm. or C.c.
Castile soap, dried and granulated	6/90
Benzosulphimid	0/20
Basic fuchsian	0/002
Oil of cassia	0/50
Oil of peppermint	0/50
Oil of cloves	1/00
Alcohol	75/00
Water	to make 100/00

A few drops added to water to be used as a mouth wash.

It will be noted that, excepting for the volatile oils present, antiseptics and disinfectants are conspicuous by their absence. As is well known, it is impossible to disinfect the mouth. Mere bacteriostatic (germ growth inhibitive) influence can be of value only as long as the agent is present; and the time that one is willing to keep the mouth full of fluid is limited.

The chief virtue of mouth wash preparations lies in their esthetic qualities: their pleasant appearance, odor and taste, which make one use them with a greater degree of pleasure and therefore more faithfully. The formula given yields a pleasant detergent.

METHOD OF SECURING MEDICAL LICENSURE IN LARGE NUMBER OF STATES

To the Editor:—I am about to enter on the practice of medicine but have no definite location in mind. By what method can I secure medical licensure in the largest number of states? Please omit my name. E. M. B.

ANSWER.—1. By taking the examination of the National Board of Medical Examiners you could obtain a certificate now recognized in twenty states. These were named in *THE JOURNAL*, April 17, 1920, p. 1100. For further information, write to Dr. John S. Rodman, secretary, 1310 Medical Arts Building, Philadelphia.

2. Take your examination in some state—such as Michigan, Indiana or Wisconsin—which has reciprocal registration with thirty or more other states. To secure reciprocal privileges, however, you will need to practice for at least one year in the state granting your original license. Full information is contained in "Laws Regulating the Practice of Medicine," which is published by the American Medical Association. A copy of this book will be forwarded on receipt of 50 cents.

SMALLPOX PITTING UNREMOVABLE

To the Editor:—Is there a remedy for treating the old lesions of the skin caused by smallpox? If so, which is the best?

HONORIO F. DELGADO, M.D., Lima, Peru.

ANSWER.—There is no way of removing the scars (pitting) of smallpox.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ALABAMA: Montgomery, July 13. Chairman, Dr. S. W. Welch, Montgomery.

ARIZONA: Phoenix, July 6-7. Sec., Dr. Ancil Martin, 207 Goodrich Bldg., Phoenix.

CALIFORNIA: San Francisco, June 28-July 1. Sec., Dr. Chas. B. Pinkham, 135 Stockton St., San Francisco.

COLORADO: Denver, July 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

CONNECTICUT: Hartford, July 13-14. Sec., Regular Board, Dr. Robert L. Rowley, 49 Pearl St., Hartford.

CONNECTICUT: New Haven, July 13. Sec. Eclectic Board, Dr. James Edwin Blair, 730 State St., Bridgeport. Sec. Homeo. Board, Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

DISTRICT OF COLUMBIA: Washington, July 13-15. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.

INDIANA: Indianapolis, July 13-15. Sec., Dr. Wm. T. Gott, Crawfordsville.

MAINE: Portland, July 6-7. Sec., Dr. Frank W. Searle, 140 Pine St., Portland.

NEW MEXICO: Santa Fe, July 12-13. Sec., Dr. R. E. McBride, Las Cruces.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. Geo. M. Williamson, 860 Belmont Ave., Grand Forks.

OKLAHOMA: Oklahoma City, July 13-14. Sec., Dr. James M. Byrum, Mammoth Bldg., Shawnee.

OREGON: Portland, July 6. Sec., Dr. Urling C. Coe, 1208 Stevens Bldg., Portland.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 6-10. Sec., Dr. Thos. E. Finnegan, State Capitol, Harrisburg.

RHODE ISLAND: Providence, July 1-2. Sec., Dr. Byron U. Richards, State House, Providence.

SOUTH DAKOTA: Deadwood, July 13. Sec., Dr. Park B. Jenkins, Waubay.

UTAH: Salt Lake City, July 5-6. Sec., Dr. G. F. Harding, 405 Templeton Bldg., Salt Lake City.

VERMONT: Burlington, June 29-July 1. Sec., Dr. W. Scott Nay, Underhill.

WASHINGTON: Seattle, July 6-8. Sec., Dr. Wm. M. O'Shea, 305 Old National Bank Bldg., Spokane.

WEST VIRGINIA: Charleston, July 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

WISCONSIN: Milwaukee, June 29-July 1. Sec., Dr. John M. Dodd, 220 E. Second St., Ashland.

REPORT OF EIGHTH EXAMINATION OF THE NATIONAL BOARD OF MEDICAL EXAMINERS

The eighth examination of the National Board of Medical Examiners was held in Chicago and St. Louis, Feb. 18-25, 1920. The written examinations were held simultaneously in the two places from 9 a. m. to 1 p. m., and the laboratory and clinical examinations in the afternoons from 2 to 5. The subjects of the examination and the relative value of each were: anatomy, 100; physiology, 75; chemistry, 75; pathology, 75; bacteriology, 50; materia medica, pharmacology, and therapeutics, 75; medicine, 200; surgery, 200; obstetrics and gynecology, 75; hygiene, 50; medical jurisprudence, 25. A percentage of 75 was required to pass. Falling below 65 per cent. in two subjects, or below 50 in one subject, constituted a failure.

There were sixty-two applicants who applied for examination. Sixty were found to have the essential preliminary and medical qualifications. Forty-eight appeared for examination, of whom thirty-six passed and twelve failed.

ANATOMY

Examiner, Dr. Herbert Harlan, Baltimore. Associate examiners in practical anatomy: In Chicago: Drs. Roy L. Moody, Ruben Strong, S. W. Ransom, Charles F. Swift and B. S. Harvey. In St. Louis: Drs. C. H. Danforth, A. G. Pohlman, R. G. Terry and D. M. Schoemaker.

Written Examination.—1. Describe the ankle-joint, including relations with tendons, vessels and nerves. 2. Describe the pancreas. 3. What are the chief muscles of mastication, and give attachments, action and nerve supply of each. 4. What nerves are most liable to injury in case of the following fractures: surgical neck of the humerus, internal condyle of humerus, clavicle, upper end of fibula, and state probable cause of injury in each case. 5. What is the site of election for ligation of the subclavian artery; reason therefor; and through what arteries is collateral circulation carried on after such ligation?

Oral Examination.—This was conducted with the use of specimens of the brain, osseous system and internal organs, and specially prepared dissection demonstrating the gross anatomy of joints and definite regions of the body; the identification of specimens of histology under the microscope.

CHEMISTRY

Examiner, Dr. Victor C. Vaughan. Associate examiners in laboratory chemistry: In Chicago: Drs. William H. Welker, F. C. Koch, W. D. Sansum and G. Tracy. In St. Louis: Drs. Ralph W. Hoffman and J. L. Bollman.

Written Examination.—(Physics): 1. Explain by drawings and description the structure of a compound microscope. 2. Explain the mechanism and the use of the ophthalmoscope. 3. What are induced electromotive forces, and what are some experimental ways of producing them? How may they be made of value?

(Chemistry): 1. How would you detect wood alcohol in grain alcohol? What chemical change takes place in wood alcohol in the human body? What poison is formed? 2. Give the most successful chemical methods of purifying drinking water. 3. Give the chemical changes that occur in the protein, fat and carbohydrate constituents of food as they pass through the body. 4. Define an amino-acid and give a list of those amino-acids which have been found in protein molecules. 5. What are the xanthin bases? Where are they found? What is their chemistry and their physiology? 6. What deposits may be found in urine and how may they be identified? 7. Give the chemistry of the red blood corpuscle. 8. What are the five food principles? Construct a daily ration.

Laboratory Examination.—Each candidate was given three samples of urine and required to make a qualitative examination of each for sugar. In the specimen containing the largest amount, a quantitative examination was required.

MEDICINE

Examiners, Drs. H. D. Arnold and W. L. Biering. Associate examiners: In Chicago: Clinical medicine: Drs. Ellis K. Kerr, Charles S. Wilkenson, C. C. McCulloch, James G. Carr, Frederick Tice, Joseph L. Miller and Joseph A. Capps. Clinical laboratory: Drs. J. J. Moore, B. O. Raulston and Ralph W. Webster. In St. Louis: Drs. George Dock, F. N. Wilson, E. P. Buddy and J. I. Tierney. Clinical laboratory: Drs. Ralph A. Kinsella and W. P. Elmer.

Written Examination.—(Answer ten questions the first seven questions are required; select three from questions eight to twelve): 1. You are called to treat a child of 8 years who has had a sore throat for twenty-four hours. Pulse, 110; temperature, 102.5; respiration, 22. There is moderate inflammation of the pharynx and tonsils, with a few small whitish spots on each tonsil. (a) What further investigation would you make for purposes of diagnosis. (b) Describe your treatment in detail. 2. A man of 60 years, complaining of intercostal neuralgia, is found to have sugar in the urine. A twenty-four-hour specimen of the urine shows: amount, 1,200 c.c.; specific gravity, 1.029; albumin, faintest possible trace; sugar, 3.45 per cent.; diacetic acid and acetone, absent; sediment negative except for a very rare hyaline cast. His diet for the same day shows 60 gm. protein; 71 gm. fats; 180 gm. carbohydrates; 1,600 calories. (a) Comment on the degree of deficiency in the utilization of carbohydrates and the probable severity of his diabetes. (b) Outline a program of treatment. 3. (a) Describe a typical case of alcoholic cirrhosis of the liver with ascites. (b) Treatment. 4. A man, aged 53, has had for six months epigastric pain, usually two or three hours after eating; recently he has vomited occasionally, but has noticed no blood in the vomitus. He has lost weight and strength. The question of cancer of the stomach arises. Comment on the diagnostic aid that may be derived from (a) gastric analysis; (b) examination of the blood; (c) examination of the stools; (d) what other methods of examination would aid toward a diagnosis? (e) Discuss briefly the question of operation, assuming that the diagnosis of cancer of the stomach has been established to your satisfaction. 5. What physical signs would you expect to find in a patient with a sacculated aneurysm of the ascending arch of the aorta? 6. Differential diagnosis between smallpox and varicella. 7. A man, aged 65, suffers an attack of right-sided hemiplegia with aphasia. Discuss the location and probable nature of the lesion and the prognosis. 8. Tuberculosis of the kidney: (a) How may it arise? (b) What would you expect to find in the urine? (c) What evidence would warrant this diagnosis? (d) Treatment. 9. Typhus fever: (a) Discuss the etiology. (b) Differential diagnosis from typhoid fever. (c) This disease was prevalent in the recent war and still exists in certain sections of Europe. What measures should be adopted to prevent its introduction into this country? 10. How would you recognize the development of an empyema in a case of pneumonia? (b) Treatment. 11. Diagnosis, prognosis and treatment of paralysis agitans. 12. Discuss the etiology, diagnosis and treatment of Hodgkin's disease.

Clinical Laboratory (one hour).—Each candidate was required to examine specimens of urine with pathologic sediments, specimens of stool and diagnose blood slides.

Clinical Examination.—This was held in the wards of the Cook County Hospital, Chicago, and in the Barnes and St. John's Hospitals, St. Louis, each candidate being assigned to a long case and then quizzed on his findings. Following this the candidate was assigned to short cases representing some well defined condition, as pleural effusion, enlarged heart, large liver, aortic insufficiency, subacute endocarditis, severe anemia, etc.

MATERIA MEDICA AND THERAPEUTICS

Examiners, Dr. W. L. Biering and Dr. H. D. Arnold. Associate examiners: Pharmacology: In Chicago: Drs. Hugh McNigan, R. W.

Keeton, F. C. Beebe, W. G. Lee and A. L. Tatum. In St. Louis: Drs. J. E. Thomas and Herbert S. Gasser.

Written Examination.—1. Describe one method of standardization of digitalis. In a case of heart failure with auricular fibrillation, outline the use of digitalis, giving the preparation, dosage and mode of administration. 2. Given a case of a man, aged 25, with the history of intermittent fever during the last ten days, the blood slide examination revealing the presence of the tertian type of *Plasmodium malariae*, write the directions for the medication indicated, giving the preparation, dosage and mode of administration of the drug used. Discuss the pharmacologic action of the drug in this case. 3. In a case of a girl, aged 14 years, with acute tonsillitis, in which the bacteriologic examination of a throat swab reveals the presence of *Bacillus diphtheriae* (Klebs-Loeffler), outline in detail the specific therapy indicated during the course of the illness. 4. The patient is a man, aged 36, with a macular eruption of the skin, acute lymphadenitis of the cervical, epitrochlear and inguinal lymph nodes and positive (+++++) Wassermann blood reaction. Outline in detail the specific medication indicated (including preparation, physical properties, dosage and mode of administration of the drugs used) during the course of treatment until the blood shows a negative Wassermann reaction. 5. Compare the analgesic value of morphin and hydrated chloral for hypnotic effect, to be administered in a vehicle to disguise the disagreeable taste of the mixture, giving full directions to the patient and indicating the dose intended of each drug.

PHARMACOLOGY

1. Demonstration experiment: A dog was prepared and various drugs injected to show effect on respiration, heart rate, and blood pressure. The effects to be interpreted by the candidate with recognition of the drug used. 2. Diagnosis of a number of tracings as to the pharmacologic effect and the character of drug producing it.

PHYSIOLOGY

Examiner, Dr. W. S. Carter. Associate examiners: In Chicago: Drs. J. T. Groat, H. P. Saunders, J. M. D. Olmstead and George P. Dreyer. In St. Louis: Drs. Frank N. Wilson, R. J. Terry and Don R. Joseph.

Written Examination.—(Answer any five questions): 1. (a) What is the cause of the rhythmic contractions of the heart? (b) Where does the contraction have its origin and how is it conducted to the different parts of the mammalian heart? 2. Describe the normal movements of the stomach and the mechanism controlling the action of the pyloric sphincter. 3. Tell how the excretion of urine may be influenced: (a) By changes in the general circulation, and (b) By changes in the circulation within the kidney. 4. (a) Describe the structural changes which take place in the peripheral end of a nerve after it has been severed and united by primary suture. (b) How much time is required for the restoration of function, and what changes take place in the electrical reactions of the muscles supplied by the nerve? 5. What results (a) from destruction and (b) from the administration of extracts of different parts of the pituitary body? 6. (a) State briefly in what ways glycosuria may be produced experimentally in animals. (b) Discuss the "sugar tolerance" test or alimentary tolerance for glucose as an index of carbohydrate metabolism in man.

Practical Examination.—Determine the blood pressure in man by the auscultatory method in the recumbent and erect postures, and record the systolic, diastolic, mean and pulse pressure in each case. Explain the effect of the postural change. Explain from tracings furnished the effects produced on respiration, pulse rate and blood pressure by stimulation (1) of the central end of a divided vagus; (2) a mixed spinal nerve. Explain from tracings the effects of applying the Gaskell clamp or the ligature of Stannius to the frog's heart. Take a tracing of the arterial pulse with a sphygmograph. Describe the features of the arterial and venous pulse in tracings furnished. With a muscle preparation arranged, record the minimal and maximal simple contractions; also complete tetanus. Explain, from the blood pressure tracings furnished, the effects of stimulating the distal end of the cut splanchnic nerve; of stimulating the depressor nerve. Demonstrate the "light" and "accommodation" reflexes of the pupil, and explain the purpose of each reaction.

SURGERY

Examiners, Dr. E. Wyllys Andrews and Col. Louis A. LaGarde. Associate examiners: Operative surgery: In Chicago: Drs. D. B. Phenister, G. L. McWhorter, Linn F. McBride, A. H. Montgomery, M. Hanchett, Gatewood, Edmund Andrews, Carl B. Doris. Clinical surgery: Drs. Karl A. Meyer, R. W. Nealy, Kellogg Speed, Frederic Besley, William R. Cubbins and F. G. Dyas. Surgical specialties: Examiners: Eye, Ear, Nose and Throat: Drs. Herbert Harlan and David Strickler. Skin: Dr. Isadore Dyer. Associate examiners: In Chicago: Skin: Drs. Edward A. Oliver and T. E. Senear. Ear, nose and throat: Drs. E. K. Findlay, D. J. Holinger, E. V. L. Brown and G. W. Boat. In St. Louis: Operative surgery: Drs. A. O. Fisher, W. E. Leighton and Max W. Myer. Clinical surgery: Drs. Edwin P. Lehman, Barney Brooks and Everts A. Graham. Surgical specialties: Eye: Drs. E. T. Sensensy, W. E. Shahan, William F. Hardy and Joseph M. Keller. Ear: Drs. H. W. Lyman, J. B. Shapleigh and C. F. Fingsten. Nose and throat: Drs. Greenfield Sluder, William M. C. Bryan and M. F. Arbuckle. Skin: Drs. M. A. Engman and Joseph Grindon.

Written Examination.—(Answer first seven questions; choose three from last five): 1. Indications for decompression of the brain: (a) Subtemporal. (b) Subtemporal. 2. Discuss the surgical management of toxic goiter. 3. Surgical management of empyema: (a) Caused by *Streptococcus hemolyticus*. (b) *Pneumococcus*. 4. Differential diagnosis of chronic obstruction at the pylorus, ileocecal valve and sigmoid flexure. 5. Treatment of gunshot wound of the liver. 6. Give indications for and technic of the operation of cholecystectomy. 7. Discuss chronic ulcer of the stomach from the standpoint of its complications and sequelae. 8. Treatment of compound fracture of both bones of the forearm just above the wrist-joint. 9. Varieties and diagnosis of dislocations of the humerus. 10. Discuss the diagnosis, prognosis and treatment of malignant pustule. 11. Differential diagnosis between shock and internal hemorrhage. 12. Discuss advantages and disadvantages of: (a) Open method of administering anesthetics. (b) Closed method of administering anesthetics.

Operative Surgery.—Each candidate was given one operation on a dog previously killed by ether from the following list: trephine; tracheotomy; thoracotomy; lateral intestinal anastomosis; etc.

Clinical Surgery.—This was held in the wards of the Cook County Hospital, Chicago, and the City and Barnes Hospital, St. Louis. Each candidate was given at least three cases and these were chosen from the following: fracture of hip; fracture of tibia and fibula; fracture of femur; supracondylar; leg ulcers; abscess of the neck; obstructive jaundice; carcinoma of stomach; carcinoma of rectum; tuberculous peritonitis; empyema, etc.

PATHOLOGY

Examiner, Dr. Louis B. Wilson; associate examiner, Dr. Eugene L. Opie, St. Louis.

Written Examination.—(Answer the first and any other four of the following questions): 1. (a) Describe in detail necropsy technic, including methods for the preservation of tissues. (b) In how many postmortems have you taken part? (c) How many more have you observed? 2. Discuss the pathology of epidemic influenza. 3. Discuss wound healing. 4. Discuss the pathology of chronic interstitial nephritis. 5. Give the distinguishing characteristics, gross and microscopic, of benign and malignant overgrowths of the uterine mucosa in women past the climacteric. 6. Contrast in parallel columns: (a) the blood pictures; (b) the gross pathologic changes, and (c) the histologic changes in pernicious anemia and lymphatic leukemia. 7. (a) Discuss the criteria of malignancy. (b) Name five tumors, giving sites, which are malignant. (c) Name five tumors, giving sites, which are not malignant.

Laboratory Examination.—During the written examination each candidate was given gross specimens and microscopic sections chosen from the following: cancer of breast, cancer of uterus, congenital cystic kidney; amebic abscess of liver; pyemic lung; lobar pneumonia; tuberculous lung; hypertrophic heart; contracted kidneys; vegetative endocarditis (*Streptococcus viridans*); aortic aneurysm; duodenal ulcer; cancer of the pylorus involving the head of the pancreas; tuberculous ulcers of the small intestine; typhoid hyperplasia of small intestine; fat necrosis; tuberculous peritonitis; colloid goiter; infarct of spleen; osteosarcoma of tibia; Pott's spine; osteomyelitis. Microscopic: cancer of breast; cancer of lip; tuberculosis of lung; chronic nephritis; tuberculosis of bone; exophthalmic goiter; cancer of uterus.

OBSTETRICS

Examiner, Dr. Austin Flint; associate examiners: In Chicago: Drs. W. G. Lee, D. S. Hillis and W. F. Hewitt. In St. Louis: Drs. A. S. Schlosstein and Otto H. Schwarz.

Written Examination.—1. (a) From the time of conception, what are the sources from which the ovum (and subsequently the embryo) draws its nourishment? (b) What changes take place in a woman at the menopause? 2. Describe the mechanism of labor: (a) In a simple flat pelvis, moderate degree, cephalic presentation. (b) In a normal pelvis, head extended, chin anterior. 3. (a) What are the symptoms indicating low implantation of the placenta? (b) Describe the management of such a case in labor at term, membrane unruptured, vertex presentation, cervix three fingers dilated. 4. What are the indications for (a) cesarean section; (b) version with breech extraction; (c) midpelvic forceps operation? 5. Describe the treatment of: (a) Puerperal septicemia. (b) Threatened eclampsia at the thirty-sixth week of pregnancy.

GYNECOLOGY

1. In a doubtful case, how would you proceed to establish the diagnosis of gonorrhea in a woman? 2. Give the differential diagnosis between: (a) Acute septic salpingitis and tubal pregnancy threatening rupture. (b) Intraligamentous ovarian cyst and fibroid of the uterus. 3. Describe in detail an operation for the repair of a complete tear of the perineum. 4. What are the indications and contraindications for the use of vaginal tampons, ring pessaries and stem pessaries? 5. Discuss the advantages and disadvantages of removing both ovaries and tubes when doing a hysterectomy for fibroids.

Oral Tests.—During the written examination each candidate was required to make demonstrations on the manikin and to explain different obstetric operations.

BACTERIOLOGY, SEROLOGY AND PARASITOLOGY

Examiner, Admiral E. R. Stitt. Associate Examiners: In Chicago: Drs. Arthur I. Kendall and D. J. Davis. In St. Louis: Drs. M. S. Fleisher and L. S. N. Walsb.

Written Examination.—1. (a) Give a simple method of culturing anaerobes. (b) Briefly discuss the subject of botulism, giving name and characteristics of causative organism, and practical importance of the infection. (c) What do you know concerning *Bacillus fusiformis*? 2. How has the recent epidemic of influenza altered our views as to the etiology of the disease? Prepare a concise statement not exceeding three pages. 3. (a) Briefly discuss the nonpathogenic acid-fast bacteria and method of differentiation from the tubercle bacillus. (b) What are the usually recognized types of tubercle bacillus, and discuss their relation to clinical types of tuberculosis in man? (c) Name the diseases in which the question of secondary infection is of importance. 4. (a) Discuss serologic methods of separating meningococcus groups from one another and from the gram-negative organisms frequently isolated from the nasopharynx. (b) Name the diseases against which prophylactic vaccination has been of value during the World War. (c) Briefly discuss methods of desensitization. 5. (a) Name the common trematode, cestode and nematode parasites of man (give only four in each group with zoological and common name). (b) How do the sexual forms of estivo-autumnal malaria differ from the nonsexual ones? (c) What is the nature of the parasite causing African sleeping sickness?

Laboratory Examination.—The examiner is provided with tubes, plates, etc., of various standard culture mediums. The candidate is examined as to the composition, uses, technic of inoculation and study of these. There are also provided plates of plain agar, blood agar, etc., showing colonies, and the candidate is examined as to his ability to recognize and discuss colony characteristics with the unaided eye and magnifying glass. Various serologic preparations, such as Wassermann or other complement fixation tests, microscopic agglutination, precipitin reactions, etc., are provided, and interpretation of these is required. Specimens of intestinal parasites and their ova, together with stained smears of blood preparation of parasites, will be given the candidate for identification.

HYGIENE

Examiners, Surgeon-General Rupert Blue, U. S. P. H. S.; Col. W. C. Rucker, Assistant Surgeon-General, U. S. P. H. S.

Written Examination.—1. What points should be stressed in the sanitary inspection of a public restaurant? 2. What directions should a practicing physician give to prevent the familial spread of whooping-cough? 3. Briefly outline the various methods of water purification. 4. Discuss mental hygiene in the home. 5. How would you prevent the spread of smallpox in a hotel?

MEDICAL JURISPRUDENCE

Examiner, Dr. Isadore Dyer.

Written Examination.—1. State generally the causes for which a license to practice medicine can be revoked. 2. Describe the Harrison act as it applies to the practice of medicine. 3. What do you understand by vital statistics, their scope and purpose? 4. State what you understand by the term "quarantine" as applied to contagious and reportable diseases. 5. A man employed in a factory, while carrying a box of goods upstairs, falls against a loosened steam pipe and is scalded over an area about 6 inches square in the lumbar region. In claiming damages he bases the claim on the severe burn received. Examination in court is ordered one year after the accident. What condition would you expect to find in evidence? (a) If he had a burn of the first degree? (b) If he had a burn of the second degree?

Book Notices

COLLECTED STUDIES ON THE PATHOLOGY OF WAR GAS POISONING. From the Department of Pathology and Bacteriology, Medical Science Section, Chemical Warfare Service. Under the Direction of M. C. Winternitz, Major M.C., U.S.A. Published with the Consent of the Surgeon General, U. S. Army, and the Director, Chemical Warfare Service. Cloth. Price, \$20. Pp. 165, with illustrations. New Haven: Yale University Press, 1920.

This magnificently printed book contains a complete review of experimental work on the pathologic changes observed in experimental animals subjected to various war gases, during the investigations carried out with these substances at Yale University and at the American University at Washington, D. C., under the direction of the Bureau of Mines and the Chemical Warfare Service. The effects of chlorine, phosgen, chlorpicrin, superpalite, "mustard" gas, cyanogen chlorid and bromid, arsin and organic arsenic compounds are described. These studies have been carried out in great detail, with especial reference to the comparative features of poisoning with the different gases. No human material is described, thus differing from the monograph on "mustard" poisoning by Warthin and Weller, recently reviewed in these columns. The importance of the breaking down of resistance to bacterial infection from mouth organisms is especially emphasized. Particular stress is laid on what the author believes to be evidence that edema within the lungs is of itself not so important a factor in causing symptoms or death as has commonly been believed. It is stated that up to 20 c.c. of salt solution per kilogram of animal, or from 200 to 400 c.c. for an ordinary size dog, can be injected directly into the trachea without harm, although the lung is so completely filled with this salt solution that the excess begins to come back. It is also stated that as much as 3,000 c.c. of salt solution has been injected into the trachea of a dog in thirty minutes without any serious harm being observed. In these experiments the lungs are flooded with salt solution, and as the solution ceases to flow out of the trachea and mouth they are again flooded; or else a continuous small stream is allowed to flow into the lung throughout the experiment. Experiments showed that the salt solution had not simply short-circuited through the bronchi and out again but had entered the alveoli extensively. The salt solution that remains in the lung after the experiment is absorbed within three or four days. It is suggested that such irrigation of the lung might even be possible as a therapeutic method under certain conditions, since materials employed as indicators can be washed out of the lungs by this means. It is not made clear how the animal escapes drowning in such an experiment, or how it is able to carry on respiration with the respiratory passages full of fluid.

The justification for so expensive a form of reproduction of research work is certainly open to question. The selling price of this book of 165 pages is \$20, which means, of course, that its circulation will be virtually limited to distribution copies and to the files of a few libraries. The expense is chiefly from the presence of forty-one large colored

plates and a great number of black and white illustrations. Even the excellence of these plates will seem to many scarcely to justify the expense of reproducing all of them, since in most respects the information given by many of the plates can be adequately conveyed by descriptions in the text. Such simple conditions as ordinary pulmonary edema or congestion of the pulmonary capillaries are made the subjects of special colored plates.

LEHRBUCH DER AUGENHEILKUNDE. Von Dr. Paul Römer, Geh. Medizinalrat, o. ö. Professor der Augenheilkunde. Third edition. Paper. Price, 30 marks. Pp. 496, with 297 illustrations. Berlin: Urban & Schwarzenberg, 1919.

The third German edition of Roemer's textbook is an improvement on its predecessors in its reduced size and in the fact that less emphasis is placed on theoretical matters. Much of absorbing interest to the specialist, however, is found along these lines, for instance, his vigorous attack on the prevailing Leber theory of the constant formation and circulation of the aqueous humor, and Grawitz's contention that the leukocytes of corneal inflammation and repair are derived from the fixed corneal cells, and that the most constant finding in fresh glaucoma eyes is an edema of the back of the eye due to a swelling of the vascular tunic. Roemer accepts the Fuchs findings in sympathetic ophthalmia, and deals a hard blow to Elschnig's anaphylactic theory in a single short paragraph. He makes the points first, that anaphylactic phenomena are in no way concerned with the origination of inflammation, as contended by Elschnig, but represent only the expression of the protective capacity of our organism against protein products, and, second, that resorption of one's own injured uveal tissue cannot lead to oversusceptibility of one's organism, because there is no such thing as autoanaphylaxis. Among the newer things, one may note the irrigation treatment in ophthalmia, the description of "inclusion blennorrhoea" in the new form, and the use of gentian violet along with zinc in angular conjunctivitis, ethylhydrocuprein in serpentine ulcer, benzosalin in sympathetic ophthalmia, and bloodletting and chloral hydrate to control acute congestive glaucoma. He gives first place among operations to trephining in both chronic congestive and simple glaucoma. There is an excellent chapter on the Wassermann reaction and another on tuberculin in diagnosis. One is astonished, however, to find "rheumatism" still given in the etiology of iritis, and no mention of focal infections. Possibly American medicine is a bit conscious of its own achievements, nowadays, but we can see no justification for ignoring the name of Buller in connection with the shield of the other eye in gonorrheal ophthalmia; of the Ferdinand Hotz trachoma operation, or of the brilliant work of Woodyatt in reducing intra-ocular tension by means of intravenous glucose injections. The work is well supplied with colored plates, and is helped by marginal notes and short topic sentences. For the first time in any eye textbook, public health matters and measures, such as school examinations, compulsory notification of gonorrheal ophthalmia, and the prevention of trachoma and eye accidents, are given the special consideration and strong emphasis they should have.

HANDBOOK OF ANAESTHETICS. By J. Stuart Ross, M.B., Ch.B., F.R.C.S.E., Lecturer in Practical Anaesthetics, University of Edinburgh. Introduction by Hy. Alexis Thompson, C.M.G., M.D., F.R.C.S.E., Professor of Surgery, University of Edinburgh. Chapters upon Local and Spinal Anaesthesia by William Quarry Wood, M.D., F.R.C.S.E., Lately Temporary Assistant Surgeon, Edinburgh, Royal Infirmary, and upon Intratracheal Anaesthesia by H. Torrance Thomson, M.D., F.R.C.S.E., Anaesthetist to the Leith Hospital. Cloth. Price, \$2.50. Pp. 214 with illustrations. New York: William Wood & Co., 1919.

This is a convenient pocket edition on the subject, useful for students taking the course. It is well written, and good suggestions are made for recognizing, and also avoiding the danger zones of anesthesia. Ross dwells lightly on several theories of shock without giving anything new or conclusive on the subject. He is instructor in a Scottish university, and he describes at length the various forms of anesthetic apparatus used at home, while giving only passing notice of those used in America. He advocates the use of preanesthetic narcotics, which is sound in practice, and is gaining in popularity in this country.

Admissibility of Evidence Touching Mental Capacity—Imbecility

(*State v. Kelsie* (Vt.), 108 Atl. R. 391)

The Supreme Court of Vermont, in overruling exceptions in this case, in which there was a conviction of murder in the first degree, says that the defendant called a physician as a witness, and, having qualified him as an expert in mental diseases, and having shown by him the examinations, observations and tests to which the defendant was subjected, he drew from the witness the statement that as a result the witness had reached the conclusion that the defendant, who was then nearly 34 years of age, had the mental capacity of a child only 8 years old. The witness was then asked how, from a medical standpoint, an adult of that mentality is classified, and replied, "As an imbecile." On motion by the state, that answer was stricken out. The witness was then asked, "From your observations and tests, Doctor, what would you say Mr. Kelsie is?" This question was objected to by the state, and was excluded by the trial court. Assuming for the purposes of this discussion that it was sufficiently apparent that he would have answered that he regarded the defendant as an imbecile, the ruling was without error. Such an answer would have added nothing to the testimony of the physician, as given. He was allowed to give, and did give, during his examination and cross-examination a very clear, comprehensive and intelligent account of the various tests that were applied to the accused to determine his physical condition and his mental development, together with his responses and reactions, and from it all gave his conclusion that the accused was mentally and morally an 8 year old boy. The purpose of this evidence was apparent. At common law an infant under the age of 7 years was conclusively presumed to be incapable of committing a crime. Between 7 and 14, he was presumed to be incapable, but the fact might be shown otherwise. Above 14, he was presumed to be capable, but this presumption was rebuttable. So if common-law rules were to be applied, the defendant had by this evidence, if believed, raised a presumption of his incapacity, and made a jury question of it. If the witness had added that he regarded Kelsie an imbecile, the statement would have afforded the jury no additional aid in estimating the man's mentality. For the term "imbecile" has no fixed meaning in the law, and would require definition by the witness to ascertain the meaning which he ascribed to it. There are grades of imbecility, just as there are grades in insanity, and in the matter of criminal responsibility, the law makes no distinction between imbecility and insanity. The test of the law in all cases is, Did the accused, as applied to the act in question, have the mental capacity to understand the character, consequences and quality of such act, and successfully to resist the impulse to do it?

Another physician was a witness for the defense, and testified that when the defendant was a child he treated him for epilepsy. When the physician mentioned first was under cross-examination by the state's attorney, he was asked if in his examinations of the defendant he discovered any signs of epilepsy, and subject to exception he replied that he did not. The only objection made to this question and answer, was that the defendant did not examine this witness regarding epilepsy. But the rule that the cross-examination is circumscribed by the direct examination does not mean that a cross-examiner is limited to the specific inquiries of the examiner. A witness may be cross-examined in respect of his examination in chief in all its bearings, and as to anything that tends to explain, characterize or modify what he has therein stated. The mental and physical symptoms and conditions of the defendant were the most prominent features of the direct testimony of this witness. Anything germane to those subjects and pertinent to the questions involved in the trial was a proper matter of inquiry in cross-examination. Specific reference to epilepsy in the examination in chief was not necessary to make proper in cross-examination the question objected to; and this ruling, too, was without error.

Care Required in Selecting and Retaining Physician*(Woody v. Carolina Spruce Co. (N. C.), 101 S. E. R. 258)*

The Supreme Court of North Carolina, on the third appearance before it of this case, affirms a judgment in favor of the plaintiff, who sued the defendant company for damages which he alleged that he had sustained through the negligence and malpractice of a physician employed by the defendant but compensated by sums collected monthly from its employees, of whom the plaintiff was one when he was injured and required the services of the physician. The court said before that the defendant was under no legal obligation to employ a physician to treat its employees, but when it assumed to do so and to deduct a monthly sum from their wages for medical attention, it was under obligation to exercise due care in selecting the physician and in continuing him in its service. To the same effect the court now holds that there was no error in instructing the jury in substance that if it found by the greater weight of the evidence that the defendant engaged the physician in question to treat the plaintiff and other employees, and after it had notice of his incompetence and unskilfulness, it continued him in its employment, the jury should find the defendant negligent in so continuing him in its employment. The defendant owed the duty to the plaintiff, after it had undertaken to secure a physician for him, to secure one of reasonable skill and ability. There was no other physician, so far as it appeared, immediately at hand, and the plaintiff had paid his assessments for the employment of the company's physician, and, though he may have had doubts as to his competence, when the president of the company assured him that the fracture was simple and that he and the physician could set the fracture as well as any one, the plaintiff was not guilty of contributory negligence, nor did he assume the risk, by trusting to the assurance of the president, under the circumstances of the case. The reply of the president was equivalent to telling the plaintiff that the company would not employ any other physician, and that the plaintiff had to take the service offered to him or go without medical treatment.

- Who Must Make Required Inquiry Before Corpses May Be Used for Dissection*(Burke et al. v. New York University (N. Y.), 179 N. Y. Supp. 626)*

The Supreme Court of New York, Special Term, New York County, in sustaining a demurrer to the complaint, with leave to the plaintiffs to serve an amended complaint, says that the action was brought by the children of a man who had died in a hospital, to recover damages for injury to their feelings due to the act of the defendant, through its medical department, in dissecting the body of their deceased parent. After the father's death his body had been taken to the morgue, which delivered it to the defendant. Now Section 316 of the Public Health Law of New York not only permits, but in certain cases requires, morgues and other institutions and persons named to deliver any corpse in their possession not placed there by relatives or friends for keeping or burial to medical institutions like the defendant. The statute prohibits such delivery or receipt, however, of the corpse of any person "known to have relatives or friends, without the assent of such relatives or friends." The court takes it that these words necessarily mean known to the institution charged with the wrongful receiving of a corpse, or, what is equivalent to knowledge, lack of reasonable inquiry. But the statute seems to place on the persons having control of the institutions mentioned and having possession of such corpses the duty of ascertaining whether any particular corpse is one "which may be delivered . . . under this section." The persons so in control in this case were those who had charge of the morgue, and the statute would appear to have placed on them the duty of making inquiry to ascertain whether the particular corpse was that of a person "known to have relatives or friends." Since it was their duty to make such inquiry, it is not apparent that any useful purpose would be accomplished by requiring the defendant to make the same inquiry over again, and, in the absence of plain language to that effect, the statute should not be held to have intended duplication of inquiry.

AMERICAN SOCIETY FOR CLINICAL INVESTIGATION*Annual Meeting, held in Atlantic City, N. J., May 3, 1920**(Continued from page 1669)***Clinical and Electrocardiographic Observations on Inversion and Other Anomalies of the P Wave**

DR. WALKER W. HAMBURG, Chicago: Eighteen cases of inversion of the P wave (migration of the pacemaker) are reported: twelve cases with normal rhythm and six cases with arrhythmia (auricular extrasystoles). Inversion of the P wave is most frequent in Lead 3; five cases showed inversion in Leads 2 and 3, and one case, Leads 1, 2 and 3; five cases showed a diphasic P; four cases, bifurcated P. Analysis of these cases discloses that the majority of them suffer with varying degrees of myocardial insufficiency and are associated with acute or chronic infectious processes. In addition, evidence of vagal influence is frequent, as shown by disturbances in respiration, effect of atropin, occurrence in vagotonic individuals, etc. Electrocardiographic study of cases showing inverted P, or of cases occurring in suspect vagotonic individuals should include the effect of (a) deep breathing, (b) change of posture, (c) atropin and (d) the effort test.

Results of Antemortem Lung Punctures in Lobar Pneumonia; Their Bearing on the Mechanism of Crisis

DRS. HENRY M. THOMAS, JR., and FREDERIC PARKER, JR., Boston: Study of lung puncture performed to hasten or confirm bacteriologic diagnosis of lobar pneumonia yields interesting facts. Incidentally, the procedure of puncturing solid lung was entirely innocuous. It was found that the mortality of patients yielding viable organisms by lung punctures after the fifth day of disease was 56 per cent., whereas patients yielding no organisms by lung puncture, no matter what day of the disease, with two exceptions, recovered. Positive lung punctures were obtained, however, just before, during and just after crisis in a few cases. These facts seem to indicate that destruction of the organisms is the first step toward recovery, but also that crisis may occur before the organisms have been entirely killed, or several days after. That definite antibacterial properties are developed in the blood has been shown by many investigators; but that these properties are in any way efficacious in combating the toxic manifestations of lobar pneumonia has not been claimed. We offer our results as further evidence that two mechanisms—antibacterial and detoxifying—act, in a measure, independently. That the second mechanism may be brought about by a sudden change in ferment-antiferment balance seems quite likely, but the possibility of true toxin-antitoxin reaction has not been definitely ruled out.

DR. FREDERICK T. LORD, Boston: There are certain considerations which suggest, as Dr. Thomas has mentioned, that a dual mechanism may be responsible for recovery from lobar pneumonia. The demonstration in small amount of protective substances in the blood at about the time of the crisis and the presence of agglutinins and bacteriotropic substances, operative against the homologous organism, suggest that humoral immunity is of importance in recovery and may serve to check the septicemia and limit the spread of the local lesion. There are, however, certain observations in conflict with the humoral theory as an entirely satisfactory and complete explanation of recovery. The humoral factors are, for example, less constantly and strikingly demonstrable than might be expected were they the sole explanation of so

decisive an event as the crisis. Blake and Cecil's observation that monkeys with experimental pneumonia may die with septicemia and the local lesion be found at necropsy to be undergoing resolution may have a bearing on this matter. In such cases it is suggestive that humoral immunity may fail, while certain local factors influencing recovery may succeed. In human cases the successive pneumonic invasion of different lobes may be observed during life, with recession of the earlier lesions coincident with the spread of the later processes. At necropsy it is not uncommon to find in the same subject several pneumonic areas in different stages of development. At times a consolidated area previously recognized during life may be found at necropsy to have undergone almost complete resolution, while one or more areas are in a stage of earlier development. Recovery from lobar pneumonia fails to confer any considerable or lasting protection against subsequent attacks. A repetition of pneumonia in certain persons is so common as to suggest that the duration of humoral immunity is short, and may actually give place to a condition of increased susceptibility. Relapsing pneumonia within a few days of crisis or lysis is uncommon; but during the last few years we have had one case of Type I, another of Type II and a third of Type III pneumonia with apparent recovery, followed by a second attack due to the same organism after an afebrile interval of only a few days. The occurrence, reported to me by Dr. Benjamin White, in three horses, highly immunized against Type I pneumococcus, of a fatal Type I pneumonia indicates that even a high degree of acquired immunity does not prevent the development and progress of a local lesion. In such cases one may assume that the local factors influencing recovery failed.

In seeking an explanation of the local factors that may influence recovery, our attention has been directed to the chemistry of the pneumonic exudate. From evidence in favor of partial isolation of the pneumonic lung, an increase in the local H ion concentration and the short viability and rapid dissolution of the pneumococcus at an equal degree of acidity, we have been led to believe that local biochemical changes may be of importance in recovery.

Catalase Content of the Blood in Different Types of Anemia

DRS. E. B. KRUMBHAAR and JOHN H. MUSSER, JR., Philadelphia: The catalase content of the blood was compared with the erythrocyte count in nine cases of pernicious anemia, eleven cases of other primary and secondary anemia, and nine normal controls. Contrary to Van Thienen's observation that the catalase content was always relatively high in pernicious anemia, we found that it was as low in this disease as in other anemias, and always lower than in nonanemic persons. The variations in different persons were roughly proportional to the differences in erythrocyte counts, so that the "catalase index" (obtained by dividing the number of cubic centimeters of oxygen liberated by 0.1 c.c. of blood during fifteen minutes by the erythrocyte count expressed in millions) gave very close averages for the three groups (pernicious anemias, 28.6; other anemias, 28; normal cases, 32.7). In anemia following experimental splenectomy the catalase content of the blood fell; when the blood picture improved after removal of a diseased spleen, the catalase content increased; but in both cases the index remained approximately unchanged.

Effect of Small Doses of Roentgen-Ray on Lymphoid Deposits

DR. JAMES B. MURPHY, New York: It is a matter of common observation that lymphoid tissue is more vulnerable to infections than are other tissues; also it is well known that in these tissues infections tend to persist and are less amenable to treatment than in other tissues. Since such a state is peculiarly characteristic to this tissue, it would seem that the lymphoid elements constitute an important contributing factor, and, if this is true, a reduction of these elements in infected lymphoid tissue might so alter the course of infection that its tendency to persist would be diminished. The utilization of the roentgen ray affords a method of approach to such an experimental investigation, since through the selective action of the roentgen ray for the lymphoid ele-

ments it may be hoped to effect a considerable reduction of them and at the same time do no injury to other tissue elements.

Infected tonsils seemed to offer suitable material to which this method of investigation might be applied, and preliminary observations on results obtained were most satisfactory. A number of patients with infected tonsils have been selected from various clinics by those in charge of the clinics and sent to us for treatment and observation. These have included types of hypertrophied and atrophic infected tonsils, with characteristic involvement of the surrounding tissues, associated with constitutional disturbances. After noting the general condition of tonsils and neighboring tissues, cultures on blood agar have been prepared from material obtained by passing a sterile platinum loop into the crypts of the tonsils, and from the postnasal vault. Immediately following this procedure, crossfire treatments of filtered roentgen ray have been given. These patients have then returned at weekly intervals for further observation, at each visit additional notes have been made and cultures again made. The original cultures from all individuals showed either hemolytic streptococci or hemolytic staphylococci.

The results following the roentgen-ray treatment are striking. After the first week the injection of the surrounding tissues has disappeared, as also has excess lymphoid tissue previously noted along the margins of the pillars; and where accumulations of tissue had been noted in the postpharynx, it is seen to be definitely lessened in amount. By the third week and after, cultures are free from the hemolytic cocci previously recovered in abundance. When tonsils were at the beginning hypertrophied, they are seen to be much diminished in size. It would seem in the light of the results briefly stated that with the elimination of the lymphoid elements from infected lymphoid tissue the course of the infection has been arrested, since no other treatment than the roentgen-ray exposure has been used. While it is yet too soon to form any opinion regarding more remote effects, from a clinical point of view the present observations form a basis for further development and present a possible method of treatment of infected tonsils other than surgical interference.

Chemical Difference Between the Young Erythrocytes from the Blood of Pernicious Anemia Cases and Normal Individuals

DRS. EDWIN LOCKE and T. E. HACKMAN, Boston: Blood specimens from six cases of pernicious anemia showing from 5 to 12 per cent. of reticulated cells, four cases of hemorrhagic (acute) anemia showing from 5 to 12 per cent. of reticulated cells, one case of acquired hemolytic jaundice with 16 per cent. of reticulated cells, two cases of pernicious anemia and four normal cases with less than 1 per cent. of reticulated cells were studied with respect to (1) the resistance of the cells to hypotonic salt solutions; (2) the oxygen consumption of the cells, and (3) proteolysis (loss of amino acid nitrogen) and creatin consumption during incubation at body temperature. The cells from the cases of pernicious anemia with an increased number of reticulated cells showed uniformly less oxygen consumption than the cells from the hemorrhagic cases, and always a marked proteolysis and loss of creatin. The cells from the hemorrhagic cases and the case of hemolytic jaundice showed no proteolysis and from slight to marked gains, but never loss, of creatin. Cells from normal individuals and from cases of pernicious anemia with less than 1 per cent. of reticulated cells showed insignificant variations with respect to oxygen consumption, proteolysis and creatin consumption (or loss). All the cases of pernicious anemia with increased numbers of reticulated cells showed a greater percentage of these cells in the lower than in the higher dilutions of hypotonic salt solutions. The reverse was true in the case of acquired hemolytic jaundice. The findings in the hemorrhagic cases were, in this respect, not constant. These observations suggest that the young erythrocytes seen in pernicious anemia are atypical and biologically less hardy than the "normal" reticulated cells found after acute hemorrhage.

- Dissociated Personality: Analysis of its Psychologic Problems. E. E. Mayer, Pittsburgh.—p. 465.

Psychosis Associated with Tetany.—From an analysis of cases, Barrett is convinced that there is no specific tetany psychosis, but that the neuromuscular disturbances and the psychosis are both the result of a toxic process affecting the central nervous system. In two cases reported by him this disturbance seems to have had some relationship to disease of the pituitary body.

Nature of Colloidal Gold Precipitating Substance.—According to Weston the colloidal gold precipitating substance in the spinal fluid of paretics is a globulin. It is not the Wassermann reacting substance and can be separated from the latter quantitatively. This explains why there may be a paretic curve in the gold test with either a positive or negative Wassermann reaction.

Neurosyphilis.—A complete recovery mental, physical, and laboratory, after less than five years or ten years or even before death Raeder says may be questioned. An apparently recovered neurosyphilitic may show none of the above signs or findings, yet at necropsy following intercurrent disease of senility, a focus of inactive treponemas may be found to occupy a circumscribed area somewhere in the brain, just as is commonly found an area of fibrosis or calcification in the lungs, the scar of a healed tuberculosis. In 428 cases of neurosyphilis treated during a period of four years, 129 cases or practically 30 per cent. showed definite benefit. One hundred twenty-five patients are under treatment in hospitals of which a certain percentage can be expected to show similar improvement. The relatives (spouses, parents, offspring) of syphilitics and neurosyphilitics form a most important group in which not only syphilis but the earliest degrees of neurosyphilis, in the presymptomatic, often entirely unsuspected, stages, are brought to light by lumbar puncture and sero-analysis. It is in these types that by far the most benefit can be expected.

Bacteriology of Soft Drinks.—In his examination of about one dozen well known soft drinks Stokes only sought specially for the colon bacillus, but many soft drinks contain variable numbers of bacteria and this large bacterial content may be explained partially by the improper sterilization of bottles. A few bacteria remaining in the bottles may increase in the small quantity of water often left in the bottle after sterilization. Dust organisms getting into the bottles may also resist sterilization even if the bottles are dried properly. This matter may be of some importance in relation to the possibility of intestinal infection, since the organisms which produce so-called food poisoning often find a favorable culture medium in the carbohydrates of these soft drinks.

Use of Dehydrated Vegetables.—From the practical standpoint, Prescott says the use of dehydrated vegetables is to be commended, providing they can be prepared from the best quality of raw material and by methods which conserve the food values to the highest possible degree. The great advantages of dehydration in making possible the utilization of materials which now goes to waste, in reducing the cost of carriage, in their easy transportability to all parts of the world, in the saving of expensive containers and in the stabilization of agriculture and the price of materials, seem incontrovertible and argue strongly for the development of this industry.

Brain in Lethargic Encephalitis.—One of the cases reported by Alexander and Allen terminated in death. Examination of the brain revealed congestion of the meninges with considerable dilatation of the veins. Over the parietal region there appeared, here and there in the pia arachnoid, a small exudate, following the course of sulci. At the base there was intense congestion with a graying yellow exudate of moderate degree in the region of the optic chiasm. Cultures taken from the exudate and from the cortex of the brain showed no growth. Smears showed red blood cells, lymphocytes, mononuclear cells and an occasional polynuclear cell. No organisms were found with methylene blue and acid fast stains. On section of the formaldehyd hardened brain, the ventricles appeared slightly dilated, but the ependyma and choroid plexuses were normal. Sections from the cortex (parietal and occipital lobes) showed in each instance considerable involvement of the meninges. The blood vessels were dilated and there was an accumulation of inflammatory cells in the pia arachnoid consisting chiefly of lymphocytes and mononuclear cells. The cortex gray and subcortical white matter showed dilated vessels, and here and there capillaries surrounded by a few lymphocytes. Sections of the base of the brain showed most marked involvement in the region of the optic thalamus. Here no hemorrhages were evident, but the capillaries were distended with blood. There was marked perivascular infiltration with lymphocytes and mononuclear cells. In places underneath the pia anachroid and in the substance of the brain an accumulation of lymphoid cells was present. In other places there was a heaping up of endothelial cells of the pia directly in contact with the brain substance. In the pons the vessels were congested, but the perivascular infiltration was less marked. In the medulla, at the floor of the fourth ventricle, the congestion was much more apparent. There were several hemorrhagic areas, the vessels and capillaries were dilated and surrounded by a perivascular infiltration of lymphocytes and mononuclear cells.

Neurosyphilis and Psychoses.—Nineteen cases are presented by Lowrey of which fourteen were undoubted cases of neurosyphilis, one case of pseudoparesis and four had negative physical and equivocal serologic findings. Of the fourteen undoubted cases only four presented clinical evidence from which a diagnosis of neurosyphilis could be made. Since neurosyphilis may exist in association with any type of mental symptoms, and since such states may exist in the absence of any of the usual signs and symptoms of neurosyphilis, Lowrey urges that lumbar puncture should be done at least in all cases which present any atypical features. It is equally important to puncture in cases with any clinical signs of neurosyphilis, since the signs may be misleading.

Hereditary Exophthalmic Goiter.—Climenko's patients were related: mother, two daughters and children of each of these—a boy, in one case and a girl in the other. The transmission was a direct one and along the female line. It is emphasized that the occurrence of exophthalmic goiter in a boy, aged 10, and in a girl, aged 6, is in itself an extremely rare condition.

Curative Effect of Influenza.—Burr's case is an example of the favorable influence exerted by an acute infection—influenza—on an illness of many months' duration, enabling a bedridden woman suffering from an old meningomyelitis, with severe cystitis, to recover sufficiently to do housework.

Birth Paralysis. H. Platt, Manchester, England.—p. 272.

Habitual Dislocation of Shoulder.—In Ollerenshaw's opinion the deltoid muscle flap operation offers the best means of overcoming the tendency to dislocation because it provides, first, a good sling bracing up the head and neck of the humerus and, second, a muscular sling which contracts when the rest of the deltoid is in action, that is to say, in abduction of the arm, in which position the dislocation occurs.

Syphilitic and Tuberculous Joints.—Roberts has observed more than 200 cases of chronic destructive joint disease with symptoms usually ascribed to tuberculosis which, from their behavior under mercury and potassium iodid, their suggestive family histories, and the presence in many of the patients of dental stigmata, it is reasonable to believe were syphilitic.

Abnormal Spur at Elbow Joint.—In Brown's case a spur formation was present on the inner side of the ulna at the joint line. The spur was so large that it overlapped and curved around the internal side of the trochlea surface of the humerus. At the tip of this spur was a small bony mass which was not connected by bone trabeculae to the spur. There was also a slight amount of hypertrophic arthritis at other parts of the joint. Flexion and extension were limited in degree.

Rupture of Appendiceal Abscess Through Back.—In Spalding's case an abscess had formed seventeen years previously half way between the vertebrae and the crest of the ileum on the right side posteriorly, which was opened without the use of anesthesia. A large quantity of pus drained at the time, and the sinus continued to discharge for nine months. At the age of 17 the sinus reopened and discharged for one month. Her health then remained fairly good until an attack of supposed "rheumatism" for which she was treated more than a year, and which culminated in an abscess opening on the outer side of the right thigh at the junction of the middle and lower third, July 1, 1918. The area continued to drain until Spalding saw the patient. At the operation it was found that a ruptured appendix had been the cause of the original abscess.

Diagnosis of Spinal Cord Tumors.—Pain was a common factor in the three cases cited by Climenko. It expressed itself differently, however, in each case. In two cases of extramedullary tumors, it was an early symptom. In one case of intramedullary tumor, it was of later development. In one case the pain was more like the type of paresthesia at the beginning, and only later did it assume the sharp, lancinating character. In the other two cases it began as a severe sharp, cutting pain, and continued all through the course of the disease. This subjective symptom, pain, is a very valuable guide when properly interpreted. In eliciting this symptom, Climenko says, the patient's psyche must be taken into consideration. The best way is to watch the patient's facial expression when the right question is put and the proper answer is given. The facial expression is particularly valuable in testing for tenderness. An essential point in diagnosis, to which Climenko calls attention, is, that in one case after lumbar puncture the patient became suddenly more paralyzed and the Brown-Séquardian syndrome became more pronounced. This is due to the fact that after a sudden withdrawal of the fluid the tumor pressed more on

the cord and produced the given syndrome. Such occurrence, Climenko believes, should be considered as pathognomonic of spinal cord tumors where vertebral disease can be excluded.

Deficient Thyroid Secretion in Gastric Ucer.—Having observed clinically that hyperacidity may be caused by faulty thyroid secretion, and cured or relieved by the administration of thyroid extract, Katz decided to try the use of thyroid extract in the treatment of ulcers of the stomach and obtained good results.

Secondary Nephrectomy.—Of twenty cases in which Chute did a secondary nephrectomy, nine were cases in which a primary nephrectomy had been done to lessen the danger to life from a subsequent nephrectomy. Seven of these nine patients presented a pyonephrosis; three due to renal stone; two of tuberculous origin and accompanied by perirenal abscess, and two nontuberculous; one of these patients also had a perinephritis abscess. There were also two large acute hydronephroses, both in children, one the result of trauma, mildly infected, the other apparently of congenital origin. Of the nine patients subjected to secondary nephrectomy only one died. This was one of the tuberculous cases with a perirenal collection of pus, and as death did not take place until about six weeks after the secondary nephrectomy, it probably cannot be charged directly against the operation; there was no necropsy but death was supposed to have been due to a more or less generalized tuberculosis. Chute feels sure that had a primary nephrectomy been carried out on these nine patients the mortality would have been much greater than it

was; that the operation of secondary nephrectomy, in spite of its increased technical difficulties was really a conservative procedure for these patients. The remaining eleven cases represent a group in which Chute did not plan to do secondary nephrectomy but was forced to do it. Four of the patients in this group had had stones removed from their kidneys. Each had a urinary sinus in his loin that had existed for periods that varied from seven months to twenty years. Three additional cases in this group illustrate errors in diagnosis in connection with renal stones that led finally to secondary nephrectomies. Only one patient in this group died, a man with hypernephroma, on whom an unsuccessful attempt at removal had been made some months before.

Sarcoma of Cerebellum.—Steuber's patient was only 8 years of age. He was under observation for one year. At the necropsy the cerebellum presented on section a sharply circumscribed, necrotic, caseated mass, replacing practically all the entire vermis, and extending well out into the cerebellar hemispheres, leaving only a small capsule of cerebellar structure varying in width from a few millimeters to 2 centimeters. The pathologic diagnosis was small round cell sarcoma.

Malignant Moles.—This paper was abstracted in THE JOURNAL, Dec. 6, 1919, p. 1796.

Early Diagnosis of Circulatory Changes in Extremities.—Bernheim suggests that physicians might well direct a little more attention to a study of circulatory changes in the extremities. If a patient complains of cold feet, pain in the feet, especially if the pain is sufficient to keep him awake at night, the state of the circulation ought to be investigated, instead of dismissing the subject with a snap diagnosis of neuritis. Neuritis it is, of course. There is most likely an inflammatory process going on in the nerves, but it is of the degenerative type and due to a lack of blood supply, an ischemia. It is an ischemic pain, a pain that is cumulative in its effect and one that is most difficult to relieve. Indeed, the pain is but the outward expression, the earliest perhaps, of blood vessel changes which become more and more profound as time goes on, until finally there is a collapse from which recovery is not possible.

Metabolism of White Races in Tropics.—During the hot season of the year a greater metabolism was observed by Young than in the cooler season, excepting on certain days in the latter, when the rate of cooling was sufficiently great to cause the subject to shiver. This greater metabolism is attributed to the effects of the ordinary activities of everyday life which had preceded the actual experiment, which in the hot, moist weather produce a greater increase in body temperature, and consequently in the metabolism, than in the cool season. These effects also are reduced much more slowly during the hot season, when the cooling power of the atmosphere is low, than during the cool weather when the cooling power is much greater. The effects of such conditions prior to the actual measurement have thus a larger influence on the level of metabolism in the hot season. With tropical heat the metabolism is at a high level on account of the increase in body temperature produced by even slight exertion, and which decreases only very gradually after the exertion has ceased. Cold may also increase the metabolism but by producing shivering and so increasing the muscular activity.

Xerophthalmia.—Attempts to reproduce the disease in animals, by means of the bacillus obtained from a case of this disease, were unsuccessful.

Effect of Malaria in Leukemia.—In myelogenous leukemia as in lymphatic leukemia, a notable reduction in the number of leukocytes coincides with the appearance in the blood of malaria parasites. This reduction is not permanent, and is rapidly effaced by treatment with quinin.

Experimental Anopheles Infection.—Blacklock and Carter have been able to infect laboratory-bred *Anopheles plumbeus* with *Plasmodium vivax*. At 28 C. infections of the gut and salivary glands were obtained; at room temperature (maximum 26 C., minimum 17 C.) gut infection only was obtained. They have also produced infection of the gut with *P. vivax* in the case of *A. bifurcatus* at 28 C. This is the first experimental evidence produced that *A. plumbeus* is capable of becoming infected with a malaria parasite.

- Discharged Soldier and Sanatorium Treatment. G. B. Dixon.—p. 67.

Treatment of Tuberculosis.—The chemotherapeutic treatment of Ellis consisting of the use of an unstable brass compound, combined with picric acid, has been tested clinically at Alton with promising results in suitably selected cases. Hitherto its value has been most apparent in certain types of lupus, particularly when heliotherapy has been simultaneously applied. Further investigation is proceeding. Gauvain does not attach the importance to the sun cure ascribed to it by Rollier and other enthusiasts although it is a useful aid to treatment in many cases, and its psychological effect is remarkable.

Predisposition in Tuberculosis.—In Delépine's opinion it is better to attach too little than too much importance to the determining influence of predisposition. Tuberculosis can be controlled permanently only by taking comprehensive and thorough measures against infection, but in doing so one must keep in mind that there are predisposing circumstances which call for special measures. It is also important to distinguish between latent or occult and manifest disease. Finally, it must always be remembered that, accidentally or not, several factors generally act concurrently, and that their relative importance varies according to circumstances.

British Medical Journal, London

- Vagasthenia. J. A. W. Watts.—p. 669.
- Acute Suffocative Catarrh. J. A. Smyth.—p. 670.

Nutrition of Articular Cartilage.—Strangeway's studies show that the articular cartilage of the joints may derive some, if not the greater part, of its nourishment from the synovial fluid. If this hypothesis is true, then the changes which are found in the degenerative types of arthritis can also be explained. The primary cause of these degenerative types will be found not in the cartilage or bone, but in changes in the nutritive value of the synovial fluid. There is evidence that changes in the nutritive value of the synovial fluid may be due to changes in the vessels of the capsule of the affected joints.

Loewi's Test in Pancreatic Disease.—In one case reported by Cockcroft this sign was negative on three occasions; 2 drops of the adrenalin chlorid brand of epinephrin solution (1:1,000) were dropped into one eye. After one hour there was no reaction, the pupils remaining exactly equal. The jaundice was found to be due to carcinoma of the bile ducts with secondary growths in the liver. Suppurative cholangitis was also present. The pancreas was nowhere invaded by the growth, nor were there any secondary deposits in it, the gland itself being quite healthy. In a second case the test was positive; marked dilatation of the pupil appeared after one hour. At the postmortem examination, there was found to be malignant disease of the head of the pancreas, which invaded the duodenum and common bile duct. There were metastases in the liver, and obstruction and dilatation of the common bile duct and bile passages. The growth in the pancreas caused stenosis of the duodenum, with secondary dilatation and hypertrophy of the stomach and upper part of the duodenum.

China Medical Journal, Shanghai

- Case of Cretinism. W. G. Lennox.—p. 140.
- Surgical Hints to Young Medical Missionaries. C. C. Elliott.—p. 144.

Intestinal Cases.—The cases cited by Mole were as follows: (1) Almost complete obstruction of the rectum, due to

dysentery; (2) a ringed ulceration of the ileum, 2 inches from the ileocecal junction, causing complete intestinal obstruction; (3) extensive ulceration of the large intestine in a case of pulmonary phthisis; (4) extensive thrombosis of the mesenteric veins in a case of cholera.

Cancer in Hainan.—It appears from Bercovitz's study that cancer in Hainan is as much a disease of the early decades of life as of the later, for which no reason can be assigned. Cancer of the penis and glands of the neck is unusually frequent; for the former an old primary sore may be the etiologic factor; for the latter no reason can be assigned. Cancer of the exposed surface of the body is very common. Inasmuch as in most cases these people wear a scanty amount of clothing, the arms, trunk and legs of men who work the fields being bare, the rays of the sun may be a contributing factor. But it is rather more likely that large ulcers, treated in the native fashion, and the sores resulting from counter irritation as practiced by the Chinese, are the etiological factors. This is all the more probable in view of the tendency to keloid formation and the universal infection of wounds. Cancer of the stomach is infrequent. The absence of certain virulent streptococcal infections which are responsible for gastric ulcer may have something to do with this; or it may be that in this case, as in cancer of the uterus, the surgeon has not seen the cases. Cancer of the uterus is infrequent. It may be that these cases have not been seen by the physician, but it seems rather suggestive that the virulent infections of the female generative organs seem to be infrequent here.

*Early Treatment of Tuberculosis by Protective Immunization. K. Shiga.—p. 239.

Studies on Bacillus Mallei.—Koga and Otsubo have proved by cultivation that *Bacillus mallei* has flagella and produces spiral bodies. These spirochete-like bodies seem to be an abnormal development of either bacillary bodies or, more probably, the flagella in a certain condition. They bear close resemblance to the involuted form of *Treponema macrodentium* described by Noguchi.

Vaccine Therapy of Tuberculosis.—The results obtained by Shiga from the use of his T. B. serovaccine as an immunizing agent in the treatment of 300 cases of pulmonary tuberculosis have been very gratifying to him. Nutrition was improved markedly, the patient gained in weight and the symptoms of slight fever and lung sounds disappeared completely. Patients seen four years after cessation of treatment were still well. This vaccine was also used after the cessation of a pleurisy, following extirpation of tuberculous kidneys and testes. Dilutions of from 1:20 to 1:5,000 were used in doses varying from 0.1 to 0.8 c.c.

*Gastrocolic Fistula. D. Firth.—p. 1061.

Infections of Hand.—Analysis of 168 cases by Molesworth showed that hand infections in working people are too fre-

quently the cause of grave disability. The time to treat these conditions efficiently is in their early stages. When tendon sheaths, etc., have become infected the hope of a useful finger is a thing of the past; the object of treatment then becomes to save whole hands, forearms and even lives. The outlook of the profession toward hands is much the same as it was toward the appendix twenty years ago. If localized tenderness became the danger signal in the hand, as it has become in the abdomen, and if suppuration in the hand, however small the area involved, were regarded as an indication for immediate operation, Molesworth says the morbidity of infected hands would fall in much the same way as the mortality of infected appendices has fallen.

Gastrocolic Fistula.—In the case recorded by Firth, a correct diagnosis was not made. The past history was indefinite, the patient had undergone no operation, and two of the most characteristic symptoms, diarrhea and vomiting, subsided on admission to hospital, so that no opportunity occurred to investigate their nature. The patient died. Firth discusses in detail a combination of symptoms which should arouse a suspicion of the existence of a gastrocolic fistula.

Ascaris Lumbricoides as Cause of Urgent Symptoms in Disease Among Children. C. Pentland.—p. 313.

Splenectomy in Splenomegaly and Jaundice.—In a case of Hanot's cirrhosis without enlargement of the liver, McConnell did a splenectomy. He says that if there is any evidence that the liver is involved secondarily to the spleen, or if the spleen is a factor in the causation or an adjuvant to the course of hepatic cirrhosis, splenectomy is indicated. His patient did very well for thirty-six hours, when she suddenly vomited a large amount of blood. Her pulse became imperceptible. Twelve hours later she vomited more blood, and died shortly afterward. The postmortem report showed that the stomach and duodenum were full of blood without any lesion whatever of their walls. This gastric hemorrhage was undoubtedly the cause of death and was in all probability due to the advanced cirrhotic state of the liver.

Syringing Ears.—Two rules are laid down by Layton: First, that water at the body temperature must be used; second, that for wax the syringing must be done hard, and for pus it must be done gently. To each of these rules there is an exception: to the first when the observer wishes to produce giddiness to test the function of the vestibular nerve; to the second when the patient has earache, and may have an acute otitis media, or other painful lesion, beneath the plug of wax.

Traumatic Pulmonary Tuberculosis.—In only two cases among 139 cases of gunshot wounds of the chest investigated by McDougall was there a history of former pleurisy or tuberculosis of the lungs. In the severe types of wound seen four or five days after infliction of the injury, it was scarcely possible to make a positive diagnosis of tuberculosis from the physical signs present. In four cases a tuberculous infiltration was suspected clinically, and was corroborated by the roentgen ray. Tubercle bacilli were not found in the sputum in any cases.

Annales de Médecine, Paris

- *Tumor of Spinal Meninges. C. Roubier and P. Brette.—p. 433.
*General Paresis Among Arabs. A. Porot and N. Sengès.—p. 444.
*Sequelae of Rachitis in Adults. A. Léri and T. Beck.—p. 449.
*Gland Extracts in Differential Diagnosis. R. Porak.—p. 469.

Tumor of Spinal Meninges.—The woman of 48 complained for six or seven months of pains in the neck and left arm. Then came spastic paraplegia and amyotrophic paresis of the smaller muscles of the hands, predominant on the left. Finally sphincter and trophic disturbances ushered in the terminal phase. The pains throughout the whole year's course were so severe that morphin was required almost daily. Nothing but compression from a tumor could explain the sequence of events, and necropsy revealed a small subdural myxosarcoma, not adherent to cord or meninges, but its anterior position would have rendered access to it extremely difficult.

General Paresis Among Arabs.—The total absence of general paresis among Arab syphilitics has long attracted attention. Not even the stress of years of service at the front brought any tendency to general paresis among the Arab troops. Porot and Sengès relate that in their experience at Alger, notwithstanding the extreme prevalence of syphilis, they have never encountered but one instance of general paresis, and this was of such a mild form that the Arab officer was able to serve for more than three years at the front, and the necropsy findings were meager.

Rachitic Adults.—Léri and Beck draw the composite picture of what they call *les petits rachitiques* from study of twenty-two such cases and forty suspects. In ordinary life there is nothing to suggest that they are not normal except that the legs are rather short, with tendency to genu varum; the teeth are irregular; the root of the nose is somewhat sunken; the nostrils wide and the mentality is backward. Under physical or mental strain their bones soon begin to ache and they whine and complain, and are listless and inert, striving to avoid every effort, even the effort of speaking clearly. This inertia during military service brought some of these men up for discipline, as they simply refused to get up when ordered, wishing to be left alone, while their statements as to their bones aching were so vague that they were not believed. This pathologic type is usually misunderstood. Such persons need peace and quiet, and they should be advised to live in the country, although even here they are liable to break down during periods of extra work, harvesting, etc. Ordinary treatment for rheumatism is of no benefit; rest is what they need until they can reassemble their forces enough for tranquil living.

Gland Extracts for Differential Diagnosis.—Porak has been studying for some years the response to thyroid, pituitary and other gland extracts in health and in disease. The difference in the reaction is often so marked as to aid in differential diagnosis. Suprarenal extract and thyroid extract in the healthy display an immediate pressure reducing and pulse slowing action, but with myxedema nothing of the kind occurs, or it is very slight, or the effect may be the reverse, the pulse becoming accelerated. In one girl of 10 with a white swelling of the knee and tendency to obesity, no effect was apparent from test administration of thyroid extract. This confirmed the suspicion of myxedema, and under regular and continuous thyroid treatment improvement was soon observed; in ten days the weight dropped from 34.3 kg. to 30. Pituitary extract accelerates the pulse in myxedema and slows it in the normal, while it causes the pulse to grow slower from the oculocardiac reflex in myxedema. The test

is made with intramuscular injection of 0.5 to 2 c.c. of thyroid extract or pituitary extract. In seven tests with suprarenal extract the blood pressure was not raised as high or as long in myxedema as in the healthy except when the myxedematous were taking thyroid treatment, in which case the response was about the same as in the healthy.

*Meningococcus Arthritis. P. Nobécourt and J. Paraf.—p. 297.
*Nodding Spasm in Children. J. Comby.—p. 303.

Meningococcus Arthritis in Infant.—Nobécourt and Paraf warn that arthritis in an infant should suggest the meningococcus. In the case reported the left ankle was the only joint involved. The child had been having slight fever for four days. There were no symptoms of meningitis but lumbar puncture was done nevertheless, and meningococci were found in the fluid. No improvement followed vigorous antiserum and vaccine treatment, which included injection of the antiserum directly into the ventricle. Necropsy disclosed an abscess deep in the brain, communicating with the ventricle by a minute opening.

Head Shaking in Children.—Comby compares recent works on nodding spasm with Herrman's report of sixty-four cases of what he calls head shaking with nystagmus in infants. The treatment, Comby reiterates, should be by hygiene alone, avoidance of every kind of nervous excitement and of sedatives such as bromids, belladonna and arsenic. Children with a tendency to rachitis should be given phosphorus and cod liver oil.

Bulletin de l'Académie de Médecine, Paris

April 20, 1920, 83, No. 16

- *The Contents of the Fasting Stomach. L. Pron.—p. 361.
*The Murderous Capacity of Heavy Artillery. R. Mercier.—p. 363.
*Viruses of Epidemic Encephalitis. C. Levaditi and P. Harvier.—p. 365.
*Congenital Dislocation of the Hip Joint. Calot.—p. 367.

Analysis of the Fasting Stomach Content.—Pron declares that sometimes analysis of the content of the fasting stomach is the only means to distinguish between ulcer and simple hyperchlorhydria, to detect the secondary nature of certain stomach disturbances with liver disease, and to diagnose catarrh. He was impressed with the infrequency of retention of food in the fasting stomach; this was evident only in 7 per cent. of his 500 cases, and it could be detected only with the microscope in 14 of these 35 cases. He first tests for the splashing sound, and found frank acid catarrh in 64 per cent.; acid catarrh without free hydrochloric acid but considerable fermentation acids in 85 cases; pure mucous catarrh, without free hydrochloric acid and blood in 29, and a catarrhal condition with transudation of serum and chlorids from the blood in 5. In 24 cases pure bile was found.

The Virus of Epidemic Encephalitis.—Levaditi and Harvier report the successful inoculation of a rabbit with virus from the cortex, midbrain and medulla of a patient with lethargic encephalitis. The rabbit showed similar lesions in the nervous system and they could be reproduced in other rabbits by inoculation in the sciatic nerve or anterior chamber of the eye. Virus from the clinical case did not prove pathogenic for the monkey and guinea-pig until after passage through the rabbit. The virus is filtrable and can be kept in glycerin or desiccated, and can be refound in the spinal cord of animals inoculated in the brain. Convalescents' serum has no neutralizing action on it.

Treatment of Congenital Luxation of the Hip Joint.—Calot declares that roentgenologic study of several thousand cases of congenital luxation of the hip joint has shown that some of the prevailing conceptions are erroneous. Treatment based on the information thus derived has amply demonstrated, he says, the importance of the new data thus learned. The primitive acetabulum in very young children belongs more to the ischium than to the ilium, and the head and neck of

the femur should be kept in a horizontal instead of a slanting position during the entire treatment. The thigh should be flexed to the extreme in the first cast. By these means we can obtain a large and stout horizontal cavity which will retain the head of the femur in this rediscovered primitive acetabulum. To prevent any adhesion between the head and its bed, he applies three plaster casts instead of leaving one on for the entire eight or twelve months. The flexion is slightly modified in the three casts, from $1\frac{1}{2}$ right angle in the first to 1 in the second and $\frac{1}{2}$ right angle in the third.

Neuropathic Lethargic Pseudo-Encephalitis. Roger and Chaix.—p. 308.
Fracture of Ulna with Luxation of Radius. Dujarier and Mathieu.—p. 311.

Surgical Intervention in Grave Forms of Dysentery.—Leveuf and Heuyer observed in Albania, in 1917 and 1918, 700 cases of dysentery that came directly from the front. Among these there were 49 deaths, or 7 per cent. This percentage might be larger if the deaths of soldiers after evacuation from the service could be included. In Prussia in 1917 there were 7,076 deaths in 58,196 cases, a mortality rate of 12 per cent. Their success with cecostomy in saving 6 in 10 extremely severe cases with tender colon and rapid aggravation of the general condition should encourage, they say, earlier operative intervention in both acute and chronic dysentery. By opening up the cecum amply, the feces are diverted away from the diseased mucosa, while it allows direct medication of the intestine walls. They operated between the eighteenth and the twenty-fifth days and found the cecostomy a comparatively mild intervention while it protected against hemorrhage and perforation, and allowed the patients to be amply fed.

- *Pathogenesis of Migraine. P. Pagniez and A. Nast.—p. 253.
*Circulation of the Cerebrospinal Fluid. V. Stepleanu-Horbatsky (Bucharest).—p. 254.

Nature and Cure of Migraine.—Pagniez and Nast report further experiences which confirm the alimentary anaphylactic nature of migraine, and how it can be warded off by a small dose of peptone before meals, to desensitize. After concluding a course of peptone, one man who had been subject to migraine since childhood, could take chocolate with impunity for a certain time, but then a smaller amount brought on the migraine. It was preceded by certain changes in the blood, the *crise hémoclasique*. Repeated blood counts showed normal leukocytosis after ingestion of the chocolate in five tests at three or four days' intervals. The sixth test showed total absence of the digestive leukocytosis, and in a few hours the leukocytes dropped from 6,000 to 3,700, with other signs

of the phase of hemolysis characteristic of anaphylaxis. Prophylactic treatment with the peptone is not always effectual in these alimentary anaphylactic reactions, but it should be given a trial, at least, as it often is temporarily and sometimes is permanently successful.

Circulation of the Cerebrospinal Fluid.—Four children from 9 months to 11 years old with grave gastro-enteritis or tuberculous meningitis were given an intraspinal injection of 1 c.c. of methylene blue in a 1:20 solution. The spread of the stain corresponded to our conceptions of the action of anesthetics injected intraspinally. The nerve roots were intensely stained but the spinal cord only on the surface. The stain evidently spread to the general circulation by way of the lymphatic glands. It reached the base of the brain and even the ventricles, and the presence of the stain in the jugular vein, cranial sinuses and venous plexuses of the skull testifies to the direct communication between the subarachnoid space and the venous system. The fluid is thus constantly and slowly passing from the center to the periphery, but there is no actual cycle of circulation.

- *Metastatic Cancer of Douglas Pouch and Rectum. A. Cade and C. Roubier.—p. 171.
Serofibrinous Pleurisy in Children. Hutinel.—p. 174.

Metastatic Cancer of Douglas' Pouch and Rectum.—Cade and Roubier report three cases of metastasis in the Douglas pouch and the rectum. The recognition of such metastases they regard of great diagnostic and prognostic importance. In the cases in which the primary cancer has not been recognized, the examination by palpation and rectoscopy will aid in excluding primary rectal cancer. As emphasized by Bensaude, if examination reveals the existence of an infiltration of the walls of the rectum, with no ulcerations of the mucosa nor proliferation, metastatic cancer of the rectum should be suspected, and the primary tumor should be sought for in the stomach. When the primary neoplasm has been diagnosed, the finding of the metastatic tumor will signify to the clinician that peritoneal generalization has taken place, while the surgeon will know that he must confine himself to a purely palliative operation or refrain from any intervention whatsoever.

Danger of Blindness after Loss of One Eye. E. Hegg.—p. 304.
*Rhizomelic Spondylosis in Girl. K. Schnyder.—p. 306.
Action of Drugs on the Intestines by Oral and by Parenteral Administration. F. Uhlmann and K. Zwick.—p. 308. Conc'n.

Spontaneous Drainage of Hydrocephalus.—Wieland relates that a 9 weeks' infant with congenital internal hydrocephalus of unknown origin suddenly developed polyuria; the weight dropped rapidly and the symptoms of pressure on the brain rapidly subsided. The fluid had forced its way through the brain substance which had been flattened out into a very thin layer at the top of the skull. The skull bones sank until the edges of the anterior fontanel overlapped. The fluid collected again soon, and after an attempt to trephine, the roentgenogram showed hydropneumocephalus, the cerebrum above as thin as paper. He compares the conditions with those of Goltz' decerebrated dog. The child drank vigorously from its bottle, cried and developed further, but is a spastic imbecile and blind. At the third month the parietal bones overlapped the frontal.

Rhizomelic Spondylosis.—Schnyder's case is unusual from the first appearance of the disease at the age of 9 or earlier in the girl, the involvement of the peripheral joints and the long failure to recognize the true nature of the disturbances. The girl is now 14.

*Tumors of the Mesentery in Children. C. L. Rusca.—p. 159.
Recent Literature on Extrasystoles in Children. P. Busacchi.—p. 178.

Mediastinal Tumors in Children.—Lorenzini reports the case of a girl of 6 who for a month had presented symptoms suggesting left pleurisy with large effusion, but the left arm soon showed edema and the displacement of the heart toward the right was not modified by thoracentesis. About 8,000 c.c. of fluid were released by puncture repeated nine times in the course of the following six weeks before the child succumbed to asphyxia from the lymphosarcoma found in the mediastinum. The pains almost throughout had been restricted to the upper left abdomen. A dry spasmodic cough had been the first and for some time the only symptom. The temperature was constantly febrile. A systolic murmur was heard in the right hemithorax evidently due to compression of the pulmonary artery. In Siccardi's case, in an adult, 34,900 c.c. of fluid were evacuated by thoracentesis repeated seventeen times in one month. A list of references to articles on mediastinal tumors and pleural eosinophilia is appended.

Tumors of the Mesentery in Children.—Rusca's patient was a girl of 6 with signs of an abdominal tumor, not tender, and dubious response to the skin tuberculin test. There was eosinophilia of 14 per cent. but the stools were free from parasites, and there was no fever, no pain, and the general condition was constantly good. The tumor was in the mesentery of one of the first loops of the small intestine and a segment of the intestine with the mesentery involved were resected, with prompt recovery. It proved to be an echinococcus cyst and it might have been spontaneously absorbed later, but there would have been danger of rupture of the cyst and toxic action from its contents. Devé and Penna have reported fatalities from this cause.

- *Protein Therapy in Colitis. A. Furno.—p. 37. Conc'n.

Dysenteriform Hemorrhagic Colitis.—In Furno's five cases there was evidently mild mixed infection, the colon bacillus predominating. From some unknown cause, possibly chilling, the virulence becomes exalted and treatment should aim to reinforce the natural defensive forces. For this he has found Nolf's proteose therapy remarkably effectual, that is, intravenous injections of 10 or 12 c.c. of 10 per cent. solution of peptone on alternate days. (Nolf described his method in *THE JOURNAL*, June 28, 1919, page 1901, and Nov. 22, 1919, p. 1579.) Furno emphasizes that by prompt resort to protein therapy the colitis is arrested before it reaches the ulcerative

stage which may be as grave a condition as in typhoid. Vaccine therapy may answer the same purpose. The reaction to the peptone is sometimes intense but is harmless if properly managed.

Archivos Latino-Amer. de Pediatría, Buenos Aires

- *Acute Meningitis. L. Morquio.—p. 1.
*Psoitis from Inherited Syphilis. Martagao Gesteira.—p. 20.
The Cerebrospinal Fluid in Differential Diagnosis of Meningitis and Meningo-Encephalic Reactions. G. Araújo Alfaro.—p. 28.
Organization of Bureau of Infant Hygiene in New York Health Department. Alicia Armand Ugón.—p. 55.

Acute Meningitis.—Morquio relates that in a recent two weeks he encountered 12 cases of tuberculous meningitis in children, 2 of pneumococcus and 4 of meningococcus meningitis, 2 following influenza and 1 otitis, and 1 with clear spinal fluid during life but necropsy revealed pus, a total of 22 cases in two week. With serotherapy the prognosis is losing its extreme gravity in other than tuberculous forms. Pneumococcus meningitis has usually a stormier and graver onset. One boy of 5 died in twelve hours. He has had cases in which everything seemed to indicate primary tuberculous meningitis but the progressive improvement and recovery eliminated this. This was particularly marked in some cases of meningitis following mumps, but in a case reported by Pelfort, two months after the mumps meningitis, actual tuberculous meningitis developed. Meningitis with poliomyelitis was always mild and promptly subsided in his experience. A syphilitic meningitis does not affect the general health so much; it may assume a chronic form with or without functional reactions; differentiation is particularly important with inherited syphilis. In the graver cases, he always found tuberculous meningitis superposed. Seicht was able to compile only 6 cases of acute syphilitic meningitis, and the diagnosis was made during life only in one of them. In one child an acute primary meningitis with slight leukocyte reaction, polynuclears predominating, subsided completely in less than ten days, but bacteriologic examination was constantly negative.

Syphilitic Psoitis.—Martagao calls attention to two children about 5 years old who both complained of pain and tenderness in the right flank suggesting appendicitis plus coxitis. The right leg was drawn up, abducted and rotated outward. There was no fever and the rapid onset seemed to exclude a tuberculous process. By exclusion, psoitis seemed the probable explanation of the symptoms and under specific treatment they promptly subsided.

*Test for Formaldehyd in Milk. A. Gallego.—p. 10.
Disturbances in the Digestive Apparatus in the Tuberculous. F. Gallart y Monés.—p. 13. Conc'n.

Fuchsin Test for Formaldehyd in Milk.—Gallego recalls that formaldehyd modifies fuchsin, transforming its red to a violet and rendering it less soluble in water and alcohol. This property of formaldehyd is proving useful in histologic examinations, and the addition of ten drops of fuchsin to 10 c.c. of milk turns the milk pink and the tint deepens to violet in case the milk contains any formaldehyd even in the dilution of 1:100,000. This test is much simpler than Denigès' technic which is based on the recoloration of previously decolorized fuchsin.

- *Surgical Treatment of Prolapse of the Uterus. F. Botín.—p. 1.
Pneumonia in Advanced Pregnancy. J. Torre y Blanco.—p. 7.
Occipito-Posterior Presentation. Macías de Torres.—p. 11.

Prolapse of the Uterus.—Botín explains how insufficiency of any one of the different factors involved in sustaining the uterus modifies the indications for correction of prolapse, so that no one method of correction can be applied to all. But he has been quite successful with ventral fixation of the uterus by the Delbet method, and declares that the mishaps

with it that have been reported and repeated by the detractors of this technic seem to be more numerous than they really are, and in many cases the abortion, etc., would have occurred without the fixation. He refers to a number of his personal cases in which pregnancy later developed without complications, but he advises such patients to keep in bed for twenty-five or thirty days after delivery, taking small doses of ergot daily, and, after the tenth day, hot irrigation and gentle massage of the uterus to promote involution without detaching the uterus from its artificial attachment. Recurrence of the prolapse seems to be much less frequent than with other methods, he says.

- *The Interstitial Cells. M. Ishihashi.—p. 39.
- *Fate of Morphin in Animal Body. I. K. Tamura.—p. 121.

Artificial Cancers.—THE JOURNAL has mentioned from time to time the success of Yamagiwa and Ichikawa in inducing the production of epitheliomas by painting the rabbit ear with tar. They here report similar research on the mammary gland. In 6 per cent. of 47 cases, repeated application of a tar-lanolin mixture was followed by changes in the tissues, as they show in ten handsome plates, which are of an unmistakable adenocarcinoid or carcinoma type. Their research is being continued with the aid of the Japanese Cancer Research Society and a special grant from the government. They say that they have never learned of an instance of spontaneous mammary cancer in rabbits. They injected subcutaneously 1 c.c. of the mixture of lanolin and an aqueous extract of tar, twice a month and later once a month, or the injection was made with 0.3 c.c. of pure tar directly into the mammary gland once a month. The rabbit with the adenocarcinoid cast four litters during the 463 days of the experiments.

The Interstitial Cells.—Ishihashi concludes his long study of the nature and purposes of the interstitial cells of the testicles with the statement that he was unable to detect any connection between the proportions of epithelial cells and the degree of development of the external sexual characteristics. The plates show the microscopic findings in these cells at different ages and in the rat under vital staining.

Fate of Morphin.—Tamura's research was mainly on the oxidation products of morphin and their action. The data presented seem to indicate that the paralyzing action of morphin is the work of the alkaloid itself, while the second phase, the stage of excitement, is the work of some product of its disintegration.

- *Immunotherapy of Cancer. C. Lewin.—p. 1233.
- *Effect of Digitalis on Diuresis. A. Jarisch.—p. 1235.

Autoserotherapy of Cancer.—Lewin relates his experience with autoserotherapy in the treatment of a woman, aged 44, who had been suffering for three years with various complications from cancer of the breast. In April, 1916, the right mamma had been amputated for carcinoma simplex. In 1917

a second operation was required, followed by roentgen-ray treatment. In April, 1918, when reexamined, vision of the right eye was almost gone, doubtless owing to cancerous metastases in the right orbit. From May 3 to May 15, 1918, the patient was given intensive roentgen-ray treatment, whereupon vision in the right eye improved and some of the nodules on the breast disappeared. In November, 1918, the nodules adjacent to the operation scar had returned, with ascites. Jan. 11, 1919, 3 liters of clear serous fluid were withdrawn from the abdominal cavity. In May, 1919, as the ascites was gradually increasing, treatment by autoserotherapy was begun. He aspirated 10 to 20 cm. of fluid from the abdominal cavity, and reinjected it under the abdominal skin. June 23, 1919, she was readmitted to the hospital, and received two or three injections of the fluid from the abdomen per week, from 15 to 20 cm. each, and at the same sitting the nodules were given roentgen-ray treatment. The nodules, in sharp contrast to their behavior following the preceding series of exposures, began to show a marked tendency to retrogress. July 15, 1919, 3½ liters were withdrawn from the abdominal cavity, part of the fluid being left in order to continue the autoserotherapy. After the puncture, several abdominal tumors, some as large as a fist, could be palpated. The patient continued to receive two injections weekly into September. The nodules gradually receded more and more, and the ascites showed no tendency to develop again. Gradually all symptoms disappeared. Nov. 26, 1919, the nodules on the breast and back had entirely retrogressed, leaving merely pigmented spots. The ascites had disappeared by October, and the tumors in the abdominal cavity had likewise completely receded. The right eye still protrudes, and is quite blind. No clinical trace of a carcinomatous disease process could be discovered then, and the appetite and general health were good as compared with the former condition. He has previously published a case of the kind in which the results were equally good from this autovaccination, and no roentgen exposures had been made.

Inhibitive Effect of Digitalis on Diuresis.—Jarisch reports two cases of syphilis of the aorta with insufficiency of the semilunar valves in the uncompensated stage, in which diuresis was inhibited by therapeutic doses of digitalis but was increased by very small doses. He thinks that owing to the increased excitability of the blood vessels of the kidney, the threshold for both the vasoconstricting and vasodilating effect of digitalis was reduced. As both patients had incipient contracted kidney, the conclusion may perhaps be drawn that overexcitability of the blood vessels of the kidney is characteristic of contracted kidney in the incipient stage. A second conclusion would be that in the presence of contracted kidney great caution should be observed in fixing doses of digitalis, and that small doses are to be preferred. In heart patients the same caution is required if the low specific gravity of the urine points to renal sclerosis.

Medizinische Klinik, Berlin

- *Operative Treatment of Duodenal Ulcer. Haberer.—p. 275.
- Effect of Epinephrin on Blood. P. Schenk.—p. 279. To be cont'd.
- *Sequels of Enterogenous Cholangitis. A. Albu.—p. 282.
- Rheumatoid Conditions with Eye Affections. Junius.—p. 283.
- Relations Between the Vestibule and the Posterior Cranial Fossa. O. Fleischmann.—p. 288.

Operative Treatment of Duodenal Ulcer.—On the basis of 205 cases of duodenal ulcer observed during the course of his practice, Haberer gives his conclusions in regard to indications for operation. It is his experience that gastro-enterostomy does not give very satisfactory results; several times after exclusion of the pylorus he was obliged to operate for peptic jejunal ulcer, so that he has come to regard this as a bad postoperative complication. Of late years he has been more and more inclined to resection of the duodenum, as with increasing experience and an improved technic the danger has been reduced to a minimum. He has performed 105 resections, 55 exclusions of the pylorus and 45 gastro-enterostomies for the relief of duodenal ulcer. In his first series, reported in 1918, he had 4 fatal cases out of 46 resections, a mortality rate of 8 per cent. In his second

series of 59 resections he has had only one fatal case, a mortality of under 2 per cent.

Sequels of Enterogenous Cholangitis.—Albu states that cholecystitis in children and others under 20 years of age is not so rare as is commonly supposed, as he has had seventeen cases during the past five years. He therefore recommends that if children have protracted, severe pains in the stomach, especially if they suggest colic, even though no icterus is present, a possible pathologic condition of the gallbladder should be considered, as in order to prevent the development of chronic cholelithiasis in children the first attack of cholecystitis should be recognized and given proper treatment. One girl of 11 had a typical gallstone colic, with pains mainly in the liver region but spreading to stomach and back. After vigorous purging she voided a soft calculus, weighing 2 gm., which consisted entirely of cholesterol. She had complained for a few weeks of slight stomach disturbance, but has been entirely well since passage of the calculus.

Improved Technic for Levaditi Silver Stain. J. Saphier.—p. 352.
Abortive Course in Case of Lethargic Encephalitis after Intralumbar Injection of Influenza Antiserum. Fendel.—p. 353.

Atypical Adiposis Dolorosa.—Grafe reports a case in which the onset of the disease at the early age of 14 was unusual, as there is only one other case of record (White) in which the disease appeared at an earlier age than 30. The symptoms were also unusual. Ordinarily the deposits of fat are tender and spontaneous pains (commonly of a neuralgic or rheumatic order) are slight, and only appear occasionally; in Grafe's case there was scarcely any pain on pressure, and spontaneous burning sensations and an inner feeling of great tension characterized the subjective aspect of the case. In other reported cases the periodicity of the pains and the fact of their appearing just before the beginning of new bunches have been ascribed to new deposits of fat infiltration, but Grafe thinks that the cause of the intermittent pains in his patient was accumulation of water in the fatty tissue, and perhaps in the musculature also. This alone would explain the intermittent swelling up of the deposits of fat and their subsidence at certain times. Bernoulli has published a case suggesting this in some respects. He called it a case of "false obesity from retention of fluid."

Formula for Determining the Relative Size of the Heart.—Geigel thinks that the main question from the clinical standpoint is not "How many cubic centimeters does the heart measure?" but "How many cubic centimeters of heart muscle are there to the kilogram of body weight?" As a rough formula for determining this ratio, he measures the size of the heart orthodiagram shadow (S) in square centimeters, multiplies this figure by $\frac{3}{2}$, divides the product by the weight (naked) in kilograms (W). The formula is thus $\frac{S\frac{3}{2}}{W}$. He

has been using this formula for five years and has found it reasonably accurate and of great clinical value. He calls it the reduced heart quotient.

Effect of Ultraviolet Rays on the Blood.—Traugott states, as the result of his investigation, that ultraviolet rays do not affect the number of red blood corpuscles in man. Under normal conditions the same number of leukocytes are found in the capillary blood and in the venous blood stream. A uniform increase in the leukocytes takes place usually following raying with ultraviolet rays provided the sitting is continued long enough (from ten to fifteen minutes); if the exposure is of shorter duration, there will be a difference between the number of leukocytes in the capillary and in the venous blood. The increase caused by the raying affects leukocytes and lymphocytes alike. Another effect on the blood from the influence of the ultraviolet rays is that it coagulates sooner. The number of blood platelets is likewise increased.

Meat of Tuberculous Cattle.—Müller opposes the idea that the basis of judging tuberculous food-producing animals should rest on whether there is a blood infection or a lymph gland infection. He thinks the criterion should be the degree of pathologic changes. In the presence of a high degree of emaciation, the carcass should be condemned as totally unfit for human consumption; otherwise, if only certain organs are affected, it may be used subject to certain restrictions.

Latent Syphilis and Changes in the Spinal Fluid. J. Kyrle.—p. 313.
Conc'n.

Early Treatment of Corrosive Esophagitis.—Salzer waits only from two to six days, that is, until the first severe symptoms from swallowing the caustic have subsided, before he begins preventive treatment by introducing a weighted bougie to ward off the development of a stricture. His twelve patients thus treated all recovered and showed no trace of stenosis when dismissed from the hospital. According to Hacker, a well known authority on the subject, more than 50 per cent. of the patients who survive the swallowing of caustic alkalis, have a severe stricture of the esophagus, and the rest, with few exceptions, mild strictures, and 33 per cent. of those who have strictures succumb from the effects. Salzer finds that by the old waiting policy, patients suffer great pain and often become greatly emaciated, whereas if early intervention is practiced it is not difficult to keep up nutrition, and the pain suffered is very slight.

*End-Results in Primary Joint Injuries. P. Erlacher.—p. 327.
Two Crossed Safety Pins as Improved Wound Clip. Hofmann.—p. 331.

Correction of Habitual Dislocation of the Shoulder.—Loeffler prevents the luxation by fastening the humerus to the acromion without opening the joint. Through a vertical incision on the outer aspect of the arm, from two finger-breadths above the acromion to the middle of the deltoid muscle, he separates the fibers of the deltoid and holds them apart with retractors. The arm is then rotated to bring the greater tuberosity into prominence, and a tunnel is made in this with an electric drill and a corresponding single hole is drilled in the acromion above. The holes are enlarged and a strip of fascia, 2 by 10 cm., taken from the thigh, is passed through the tunnel in the tuberosity and one end through the acromion, the ends being brought together over the acromion and sutured, end to end. The arm in the case described can be lifted to 85 degrees and rotated, and further functional improvement may be anticipated.

Intraperitoneal, Cervical Cesarean Section. Lichtenstein.—p. 343.
*Ascaris Lumbricoides in Fallopian Tube. P. Nacken.—p. 346.

Puerperal Inversion of the Uterus.—Engelmann states that inversion of the uterus seems to be getting more common than published statistics would indicate. On the basis of observations of three cases he holds the view that the Credé method, which seems to be universally used in cases of hemorrhage from atony of the uterus, may easily lead to inversion of the uterus. He therefore suggests that the maneuver be done with both hands and outstretched fingers, which he finds minimizes the danger. Unless there is pronounced shock, he recommends immediate reduction of the inverted uterus under ether narcosis.

Ascaris in Fallopian Tube.—Nacken reports a case in which a dead ascaris, 25 cm. long, was found in the suppurating fallopian tube.

*Sweating Procedures and Secretion of Urine. H. Brütt.—p. 266.

Effect of Sweating Procedures on the Quantity of Urine and on Its Specific Gravity.—Brütt has been experimenting with the view to so modifying the Volhard test for the concentration activity of the kidney that in place of the dry-food diet that the test requires a sweating procedure may be substituted. He found that all healthy subjects did not react alike to the various sweating procedures. In some a maximal concentration of the urine was produced; in others a marked polyuria with very low specific gravity occurred, while in others, again, no appreciable effect was noted. While it was evident that a sweating procedure could not in all cases be substituted for the Volhard test, the experiments showed that in applying sweating procedures to kidney patients if a specific gravity of 1.030 for the urine could be shown, we are justified in assuming that the concentration activity is satisfactory. But if there is no increase of the specific gravity, or if there is a decrease, either with or without an increase in the quantity of the urine, no definite conclusions can be drawn in regard to the functional capacity of the kidney. Only the positive result is decisive—and it is only in a small proportion of these cases that such a result is secured.

*Xanthochromia in Cerebrospinal Fluid. A. Wallgren.—p. 303.

*Etiology and Pathogenesis of Sciatica. F. Lindstedt.—p. 318.

Xanthochromia in Spinal Fluid.—Wallgren regards the hemorrhagic tendency of epidemic meningitis as one explanation of the xanthochromia observed in the cerebrospinal fluid. Or the xanthochromia may come from stagnation of the spinal fluid from obstruction of communication with the cranial subarachnoid space. In 103 cases of epidemic meningitis at the Upsala hospital in the last five years the mortality after the first twenty-four hours was 19.6 per cent., but it was only 14.8 per cent. among the 74 without xanthochromia while it was 39 per cent. among those with xanthochromia. The total mortality in these groups was respectively 28.3 per cent. 25, and 42.1 per cent., testifying to the gravity of the cases in which xanthochromia is observed. It forms part of what he calls the syndrome of Froin, that is, the spinal fluid is frankly yellow, with abundance of albumin, coagulates *en masse*, and contains numerous mononuclears. It not only throws light on the prognosis, but warns of the necessity for intraventricular injection of the antiserum if the condition is not improving under spinal injections. More attention should be paid to serotherapy by the vein in these cases, as epidemic meningitis is a general septicemic condition, not confined to the meninges. The details of six cases are described to sustain these conclusions and two pages of bibliography are appended. The article is in French.

Sciatica.—Lindstedt declares that it is impossible to draw the line between neuritic, myitic and neuralgic symptoms in sciatica, and states that in practically all of his 100 cases he found abnormal conditions of traumatic, inflammatory, neoplastic or varicose nature in the bones, joints, or soft parts of the legs, back or pelvis, usually near the course of the sciatic nerve, or else deformity of some kind or static anomalies. The nature, the localization, the chronology and the frequency of changes of these kinds in his cases of sciatica testified to a causal connection, the irritation from these abnormal conditions entailing in time a functional overexertion of that part of the central sensory nervous system involved, until it gets the "neuralgia habit" from the constantly recurring irritations from the periphery. This conception of sciatica opens new horizons for treatment of both sciatica and lumbago, and explains the benefit from empiric measures and also the neurotic or psychic factor prominent in certain cases. The article is in German.

Aseptic Renal Pyuria.—Runeberg was surprised to find that in only 33 per cent. of his 56 cases of aseptic renal pyuria was tuberculosis responsible. In 12.5 per cent. a calculus was a factor. An individual predisposition rather than any special causal agent is involved in this hematogenous pyelitis persisting interminably. The staphylococcus was most often responsible in his cases. The pyelitis is abacterial only because it does not reach us in the florid stage; sections of the kidney usually reveal the bacteria. His histologic and clinical experience has demonstrated, he says, that the blood borne infection induces first a glomerular nephritis, sometimes too mild to induce appreciable symptoms; then elimination of bacterial and waste products entails foci in the kidney tissue and an elimination pyelitis. Interstitial nephritis develops gradually from this, with subcapsular foci and possibly complicating thrombotic and embolic processes. It seems to conflict with this theory, he admits, that 17 per cent. of the 23 men in the 30 operative cases had prostatitis, but we know that urinary disease is a disease of an apparatus not of a single organ. Examining the pus in the urine of 10 tuberculous and 10 of nontuberculous abacterial pyuria and a large number of other pathologic conditions in the urinary passages, Runeberg found striking and characteristic changes in the leukocytes only in the tuberculous cases. The leukocytes showed uneven, polyhedral, gnawed edges, and they took the stain badly, while with other infections they were usually round and stained normally. With tuberculosis, the nuclei may drop out and vacuoles appear. Acute onset and alternation of symptoms and free intervals testify further against tuberculosis, but if the unilateral pyuria is sapping the patient's vitality, nephrectomy is indicated as the kidney will usually be found malformed or otherwise congenitally inferior. This was manifest in 3 of his 10 nephrectomy cases. His experience has confirmed the prompt subsidence of the symptoms of cystitis after nephrectomy for blood borne pyelitis, proving anew the integrity of the bladder. In 2 cases an abacterial pyelitis flared up and bacteria appeared in the urine under the provocative influence of operative measures elsewhere. This secondary flaring up of this elimination pyelitis might prove misleading in some cases.

Treatment of Postdiphtheric Stenosis.—Bardy reviews his experience with stenosis of larynx or trachea rendering it impossible to discard the tube. From five to fifteen months was required for the progressive dilatation, and any method will succeed, he says, if perseveringly applied. The tracheotomy tube has to be worn during the whole period of dilating as acute edema is liable to develop otherwise. He found Schmiegelow's translaryngeal permanent drain method difficult to apply to small children and liable to set up inflammation. The diphtheria in itself, without intubation, may induce necrotic processes responsible for stenosis, as in one of his cases, but as a rule the stenosis develops at the end of a tube. The mucosa in diphtheria seems to be exceptionally sensitive to mechanical irritation.

*Nail Extension for Old Fractures. E. Nielsen.—p. 177.

Action of Light on Vitiligo. C. With.—p. 182.

Nail Extension for Old Fractures.—Nielsen cut away the callus and reduced the overlapping stumps in two cases of fracture of the femur which had healed three or four years before with a shortening of 6.5 to 7 cm. He then applied weight extension from nails driven into the bone, and the deformity was corrected, the shortening being reduced to 1 and 1.5 cm. Except for a little pressure necrosis, there were no mishaps; the nails were removed the twenty-first day. The only inconvenience from the method was from the counter pressure in the perineum and axillae. The counter pressure was aided by raising the foot of the bed.

THE FUTURE OF PEDIATRICS *

FRITZ B. TALBOT, M.D.

BOSTON

I have chosen the "Future of Pediatrics" as the subject of this address because I desire to emphasize the fact that our specialty is no longer one in which a group of physicians have problems which are of interest only to themselves, for these problems are intimately connected with the welfare of the community and the nation. Since thoughtful people, both in and out of the profession, are bound to give pediatrics even greater consideration in the future, it is well that we should consider the possibilities of future development in the advancement of our own knowledge, and especially in the improvement of the general welfare.

Although this subject can be considered from many equally important angles, there is not sufficient time to discuss them all. Let me, therefore, outline the whole and then consider in detail the most important problems which present themselves to the specialist in the diseases of children. These problems should be considered from the point of view of (1) the medical schools, (2) the practitioner and (3) the public.

Research into the nature, cause and prevention of disease is assuming an importance not recognized a decade ago. It has added knowledge which has made it possible to cure many diseases which were often fatal. Such advances have been made in our knowledge that our conception of many diseases have been entirely changed. Our knowledge of what normally takes place in the body has been so enlarged that we now have a better standard with which to compare pathologic physiology. As a result of this new knowledge we are now able to treat and prevent disease more efficiently than ever before. The returns from effort and painstaking research in the laboratory, and in the field, have been so great that they have more than justified the money spent in this manner, and have made it possible to expand the work tremendously. The accomplishments of those medical schools which already have well endowed departments of pediatrics will undoubtedly stimulate expansion in other schools. We may expect the future to give still more generous support to our young men, and, as a result, to see America assume the world's leadership in pediatrics. Research, therefore, plays an important part in the study of the nature and cause of disease, and it also plays an equally important part in the study of the prevention of disease.

Preventive pediatrics, which in the past was the object of many studies, received great impetus during

the war. The annual meetings of the American Child Hygiene Association have been devoted to preventive pediatrics. The object of the campaigns and propaganda of the "Children's Year" was to increase the interest in preventive pediatrics in every home in the United States. Finally, the conference of the League of Red Cross Societies, which met in Cannes, France, April 1, 1919, brought together men interested in public health from France, Great Britain, Italy, Japan and the United States. Child welfare, or preventive pediatrics, next to stopping the epidemic of typhus fever then prevalent, was given the place of greatest importance by this group of scientists. The tendency of the present, therefore, is to emphasize the importance of the child as the citizen of the future. The part which preventive pediatrics will hereafter play will undoubtedly be so great that medical schools as well as physicians will be compelled to adapt themselves to their changed relations to the public.

Any effort to improve the welfare of children should bring results which will yield far greater returns than efforts directed toward improving the welfare of adults; the establishment of correct habits in a healthy child ought to insure a healthy adult life. This may be accomplished in two ways: either by training the individual child, or by training groups of children as in public child welfare clinics. It is especially important that this work be done during childhood, because it is now believed that many, if not most of the diseases of adult life originated in childhood. Think how much indigestion in the adult could be prevented if proper dietetic habits had been learned during childhood. Think of the deafness, the blindness and the other crippling diseases which could have been prevented if treated skilfully during the age of life which comes under the charge of the obstetrician and the pediatrician. There is much evidence that tuberculosis and endocarditis first gain entrance to the body in childhood. How much easier it would be to cure these diseases at their inception than to cure them after the various organs have been invaded and damaged by them.

The magnificent work done in preventing malaria, yellow fever and typhoid shows what a great saving in life and national efficiency can be accomplished by preventive work. Such examples should be sufficient to emphasize the importance of preventive pediatrics, from the further advances of which results, even beyond our dreams, may be expected.

Advances may be expected from medical schools, practitioners, public health officers, public health nurses, social workers, and the public itself. The public was awakened to its responsibility to the child by the recent campaign of the Children's Year and the terrible sufferings among the children of devastated countries during the war, and we must be prepared to

* Chairman's address, read before the Section on Diseases of Children at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

meet the new demands with sane and balanced judgment.

The problems should be worked out in those educational centers in which the medical school forms the nucleus. The advances can first be made by those medical schools in which the proper methods can be worked out, and taught to students who later graduate and devote their lives to their application. In most medical schools the teaching of preventive medicine as applied to child life is almost entirely lacking. In the few that give it any attention whatsoever, so little time is allotted that the student hardly becomes interested. It is only when this student graduates that he appreciates how woefully lacking is his education in a phase of medicine that makes up so large a part of his work with children.

The physician is often called in to advise the mother as to how to nurse her baby. How many young graduates have not been taught this but have been obliged to learn it by experiment on their patients? Too often they find it easier to wean the baby than to go through the trouble of straightening out the mother. How many babies' lives could have been saved if the physician understood the physiology of lactation and had had experience in the art of handling the nursing mother. There are more opportunities to use such knowledge than to recognize and treat rickets. If, however, the student acquired and used such knowledge successfully he should have little or no rickets among his own patients to treat. If this medical student is multiplied by the thousands that graduate each year, it should not be long before a marked diminution in the number of cases of rickets throughout the country would be seen.

We are all called on to regulate the artificial feeding of infants. In fact, almost the first thing we are called on to do in practice is to regulate the feeding of a normal infant. Of my first thousand cases seen in private practice 264, or more than one quarter, were for the regulation of their feeding. Although five or ten years ago this may have been true only of the specialist in pediatrics, today it is becoming equally true of all general practitioners. These general practitioners are always anxious to have papers read to them on infant feeding, and it is evident that the public is demanding of them greater knowledge of this art.

A century ago, Underwood¹ said that "a very principal cause of the above mentioned neglect has arisen from an ancient idea, for a long time too generally entertained, that, as medical people can have but a very imperfect knowledge of the complaints of infants, from the inability of children to give any account of them, it is safer to trust the management of them to old women and nurses; who at least are not likely to do mischief by violent remedies, though they may sometimes make use of improper and inadequate ones." This applies all too commonly today. The feeding of normal infants is a subject the teaching of which is woefully lacking in our medical schools. In some schools, as a requirement for the degree, the student must deliver twelve infants. I believe that he should also be required to regulate the feeding of twenty infants during at least a six months' period so that he will be familiar with the feeding of both naturally and artificially fed infants. This work should be done under competent supervision, and would give the prospective practitioner that familiarity with the

subject which can never be obtained in lectures or books. If he were also given suitable training in the normal physiology and care of the infant and young child (and experience in their care), there would be less need for the knowledge of those diseases which now results because of the lack of this training. It is much easier to keep a healthy baby well than to cure one of infantile atrophy.

This improved instruction and training could be best accomplished by making the child welfare and baby hygiene stations an integral part of the medical school. Such well-baby clinics and clinics for the runabout child could be manned by the staff of the medical school and used in teaching.

Much of the teaching in medical schools today is on subjects which have less and less practical importance. When I was a house officer from 1905 to 1907, there were always several patients in the hospital with typhoid fever, often including one or two unfortunate nurses or house officers. With the advent of preventive inoculation, and the more advanced practice of the principles of public hygiene and sanitation, typhoid fever (in my community at least) is becoming almost as much of a medical curiosity as is smallpox.

Several years ago, a successful practitioner in a summer resort told me that the previous summer he had had 120 patients with infectious diarrhea, of whom several died. The next summer, with the establishment in that community of a certified milk dairy, he had less than a dozen cases. This experience is not unique because the wards in my hospital which used to be full to overflowing with infectious diarrhea now receive only five or six cases each summer.

Since the character and incidence of disease is changing, the type of teaching should be modified to conform with our increasing understanding of the factors responsible for this change. If many diseases are fast becoming extinct, could not that time which is now being spent in teaching the methods of their treatment be used to greater advantage in teaching the methods of their prevention? The greater part of the teaching in medical schools today is directed toward the diagnosis and treatment of disease. I doubt whether one fiftieth of it is directed toward the prevention of disease among children. I believe that at least one quarter and probably more of the time should be spent in teaching the normal physiologic processes during growth, and that adequate instruction should be given in the personal and public hygiene of children. Such a program could be carried out efficiently only by the close cooperation of all departments of the medical school. The relative importance of all the subjects in the students' curriculum should be carefully weighed and balanced, and adjustments made to meet the changing times.

Although the medical supervision of the infant has been emphasized above, there is much that is lacking in the supervision of the child. Many diseases do not find a foothold in the body if the child lives in proper surroundings, has a suitable diet, and learns good and regular habits. This applies both to the home and to the school. If the physician is taught what is normal for the healthy growing child he can influence both the home and the school life. A thorough understanding of all the factors which make up a healthy home life cannot be had unless the "social" elements involved are studied and understood. A generation ago this

1. Underwood: *A Treatise on the Diseases of Children; with Directions for the Management of Infants from the Birth* 1:xxii, 1811.

understanding formed an essential part of the art of medicine as intuitively practiced by the "family doctor." In hospitals and in our own highly organized and specialized lives, it was almost a lost art until "social service" made it not only an art but also a science. The social element of medicine could well be taught along with the scientific aspects of medicine at the bedside, and thus revive that element in our professional life in which we should have a just pride.

The department of pediatrics cannot isolate itself from the other departments in teaching preventive work but, on the contrary, should cooperate with them all. The department of obstetrics could well introduce the whole subject by teaching in lectures and practice the theory and practice of prenatal care. It would be ideal if the same student could oversee the prenatal care, deliver the baby, and supervise its feeding, during the first five or six months. In this manner he would gain experience in what later he must do in actual practice. (There should also be cooperation between the department of pediatrics and the department of preventive medicine, and consideration should be given to school hygiene.)

After graduation, every practitioner should apply the principles of the prevention of disease. In those communities in which he is a pioneer, he should organize child welfare stations so that the poor as well as the rich will profit by his knowledge. The public is already prepared for such work and will welcome it, and perhaps even demand it. The practitioner need not fear that the application of these principles will decrease his income. On the contrary, although he will treat fewer sick children, he will have an increasing stream of children coming to his doors to be kept well. He will have the satisfaction of knowing that he has played a small part in diminishing suffering, in increasing efficiency, and in preparing the manhood and womanhood of our country for any emergency which the future may have in store for us.

311 Beacon Street.

OBSTRUCTION OF THE HEPATIC VEINS*

C. F. HOOVER, M.D.
CLEVELAND

My interest in this subject was aroused by a patient who entered Lakeside Hospital, Nov. 22, 1918:

CASE 1.—The history which the man gave at the time of entrance was that he had been ill for about two weeks prior to entrance to the hospital. His essential complaint was severe pain, which started about the suprasternal notch and followed in the midline to the epigastrium. The pain was accompanied by cough and a choking sensation, and he also discovered that slight exercise caused marked air hunger. The temperature on entrance had an evening rise of 101.5, and morning remissions to 100 and 99. The pulse rate varied between 100 and 120, and the respiratory rate was between 20 and 30 a minute. The physical signs at the time of entrance revealed pericarditis with moderate accumulation of fluid in the pericardial sac. In addition to this, there was some dulness and impairment of excursion at the base of the right thorax, which was accounted for in the personal history by an attack of pleurisy one year before

admission to the hospital. On that occasion about 1 pint of clear fluid was removed from the right pleural cavity. On entrance to the hospital, the patient's liver occupied a position in the nipple line 5 cm. below the costal margin. The edge of the liver was not accessible, and as there was symmetrical inspiratory narrowing of the subcostal angle, the interpretation at this time was that the liver was displaced downward by an enlargement of the pericardial sac. There was not a sufficient amount of fluid in the pericardial sac to compress the left lung in the infrascapular region.

Within ten days after admission, the evidences of pericarditis were subsiding, the inspiratory narrowing of the subcostal angle had disappeared; and by the third week all evidences of pericarditis and effusion in the pericardial sac had vanished. December 6, the patient passed two intestinal parasites, which proved to be *Taenia saginata*. The temperature varied between 99.5 and 102. The leukocyte count was 1,200; the red cell count about 4,800,000, and hemoglobin, 65 (Tallqvist). Blood cultures were made from venous puncture and proved to be negative.

About ten weeks after entrance to the hospital, the only physical sign that the patient presented was an enlargement of the liver. There was no cause for displacement of the liver, but it still extended well below the costal margin. There was no icterus or intestinal hypocholia. The blood was centrifuged and the serum found to contain no bilirubin. Therefore cholemia, choluria and intestinal hypocholia were all excluded. Although he still had moderate elevation in temperature, the only physical signs that could be associated with infection were the evidences of enlarged liver. Unfortunately, it is not accurately known just how much the lower border of the liver rose directly after recovery from effusion in the pericardial sac. That the liver dullness lessened during this period of recovery from the pericardial effusion is definitely known, but the amount is not accurately recorded.

February 8, about the end of the thirteenth week of hospital residence, the patient developed violent pain across the upper abdomen. There was no rise of temperature, and the cardiorespiratory functions were normal. The patient's pain was intense, and required the use of morphin. The following day the liver had greatly enlarged; it had become much more resistant and was very sensitive to pressure, and the lower border occupied a position about six finger breadths below the costal margin. Within twenty-four hours after the onset of this very acute pain, which was accompanied by a rapid and painful enlargement of the liver, there was also an accumulation of free fluid in the abdominal cavity, and moderate edema of the left leg and ankle. The second day after the onset of this attack of acute pain, puncture of the abdominal cavity was performed and 20 c.c. of opalescent fluid, slightly blood-tinged, was removed. The cellular contents showed about 9,000 red and 1,000 white cells per cubic millimeter. The white cells were about equally divided among the large mononuclear, small mononuclear and polymorphonuclear cells.

The acute pain and tenderness subsided in the course of several days, but the ascitic fluid continued to accumulate, until about three weeks after the acute attack of pain, when 4,100 c.c. of fluid were removed from the abdominal cavity. The fluid was slightly turbid and opalescent; did not coagulate on standing; the specific gravity was 1.014, and there were 10,000 cells per cubic millimeter, 160 of which were white blood cells. Nine days later 5,300 c.c. were again removed, with the same character as the first.

The abdomen has been tapped twenty-seven times in the last year. The character of the fluid has always been the same; but the fluid has been accumulating at much longer intervals during the last five months. The man's physical condition has steadily improved, and now the only evidences of disease are ascites and the slight elevation in temperature associated with a hepatic enlargement. The liver is no longer sensitive. There are no irregularities on the edge or on the surface of the liver. The edge is slightly rounded. On entrance to the hospital the spleen was not enlarged, but within a few weeks after the first attack of pain with acute hepatic enlargement, the spleen became enlarged and remains now palpable at the costal margin.

* Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints.

* Read before the Section on Practice of Medicine at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

In reviewing this case we can say that the man, one year before entrance to the hospital, had pleurisy with effusion of the right side, from which he made a prompt recovery, and then a few weeks before entrance to the hospital, there developed a pericarditis with effusion. As the pericarditis subsided, there suddenly developed an acute painful enlargement of the liver, which was unassociated with any new evidence of infection or any evidence of disease of the hepatic parenchyma or peritoneum. There was no evidence of disturbed production or excretion of bile. This was at a time when the heart's function was perfectly competent.

The only manner in which this collection of phenomena could be explained would be by some obstruction to the passage of blood through the liver. The enlargement was due to blood stasis within the hepatic and portal veins. If the rise in pressure within the radicles of the portal vein had been due to obstruction within the trunks of the portal vein, there would have been no acute enlargement of the liver. One cannot conceive, in fact, of the blood stasis originating elsewhere than in the large trunks of the hepatic vein. Obstruction of the hepatic veins offers the only satisfactory explanation for such an acute and pronounced enlargement of the liver, accompanied by stasis in the radicles of the portal vein and without disease of the hepatic parenchyma. Although the logic of the clinical evidence was inescapable, the diagnosis was made at the time with many misgivings on account of want of knowledge of the subject.

CASE 2.—A man, aged 31, admitted to the hospital, Aug. 21, 1919, up to the onset of his present illness had always been vigorous and strong. In March, 1914, he had an acute infection with a rise in temperature to 104. He was confined to his bed only four days. With the exception of lethargy and drowsiness, which persisted throughout the entire summer, he cannot recall any very distinct symptoms. How long his fever lasted is not known. We know only that during the acute period his temperature rose as high as 104. During the winter of 1914-1915, he was able to work, although he suffered from air hunger with moderate exertion, and a sense of constriction about the epigastrium, which was relieved in a short time by rest. In the spring of 1915, he was feeling depressed and sick, and was quite surprised when, after moderate exertion, he suddenly vomited all the contents of his stomach without the slightest premonition of nausea. The vomiting was projectile in character, and proved very embarrassing to him by occurring in street cars and public places, and attended vigorous exercise or unusual efforts in laughing or coughing. The vomiting originated purely through nervous excitation in the vicinity of the diaphragm, and was brought on by unusual phrenic activity.

In the winter of 1915-1916, he worked very little and his strength gradually improved. In March, 1917, he was put on the police force. He was quite vigorous and was able to handle recalcitrant prisoners, but even during this period the projectile vomiting would occasionally occur. In February, 1918, he found he could not continue his work. Medical examination at that time revealed an enlarged heart and a large liver. In June, 1918, he gave up his work on account of dyspnea with slight exertion, swelling about the epigastrium and fullness in the precordial region. His feet and legs and abdomen, and at times his chest and neck, were edematous. There was no cyanosis.

In January, 1919, he apparently received very much benefit from mercuric therapy, which was given on the assumption that he had had a syphilitic infection. He says that at that time the liver became smaller. In March, 1919, he was well enough to be about. His edema had disappeared and he was comparatively comfortable. In June, 1919, he went to work as a shop policeman. Then the upper half of the abdomen

swelled; he became short of breath, and the medicine which previously had benefited him failed to give relief. He then entered Lakeside Hospital. He says there was no jaundice at any time during his illness, and he thinks he had no fever except in 1914, and he has had no nocturnal dyspnea at any time.

When he entered Lakeside Hospital, he had marked edema of the lower extremities and the abdominal wall. The liver dulness was 22 cm. in the right nipple line. The surface of the liver was perfectly smooth. The edge was not palpable; it was somewhat rounded, although the consistency was quite like that of hepatic cirrhosis. The enlargement of the liver was uniform. The spleen was palpable at the costal margin; it was firm and plump. On admission there was an abundance of free fluid in the abdominal cavity, and there was some fluid in the right pleural cavity. In October there was no fluid in the left pleural cavity, but the right pleural cavity was tapped, and 1,100 c.c. were removed. It was pale straw-colored, did not clot, and was very clear. It contained only 630 cells per cubic millimeter, only 20 of which were white cells, and the specific gravity was 1.008. There were only 2 gm. of albumin per liter by the Esbach test. Although the evidences of thickened pleura were pronounced and pleural frictions were abundant, after the removal of the fluid there was no pain. Although there were evidences of thickening of the pleura of the left side, no fluid was ever obtained.

About 5,300 c.c. were removed from the abdominal cavity, and it was identical in character with that removed from the pleural cavity. So the fluid from both serous cavities was decidedly that of a transudate, although there were never evidences from the kidney or from the heart which would account for retention of body fluids. There were marked evidences of anastomotic dilatation of the radicles of the veins of the upper thorax and the superficial epigastric veins, and from the first it seemed evident that the accumulation of fluid in both pleural and peritoneal cavities was the result of stasis in the radicles of the azygos and portal veins.

Since his residence in the hospital, repeated employment of antisyphilitic treatment and large doses of digitalis have failed to modify the accumulation of ascitic fluid, although there has been no return of the fluid in the pleural cavity. The abdomen has been tapped thirty times, and there never has been evidence in the fluid to indicate peritoneal inflammation. The blood plasma has failed to show any bilirubin, and there has been no urobilin in the urine. The general edema has entirely disappeared. The patient's heart is of normal size, with no evidence of any myocardial incompetence. The great enlargement of the liver and the persisting stasis in the portal vein unaccompanied by any evidence of disease of the hepatic parenchyma, together with the evidences of stasis in the inferior cava, which has gradually been compensated for by anastomosis, justify the diagnosis of obstruction of the inferior cava with obstruction of the hepatic veins.

It is not difficult to understand why medical literature is very meager on the subject of the hepatic veins. They are not examined as a routine at necropsy, and when they have been studied it has been usually in histologic sections. The gross appearance of the intrahepatic portion of the cava and the opening of the hepatic veins are not studied at necropsy. The literature on the subject contains about thirty cases, and teaches that obstruction of the hepatic veins may be caused in several ways. The cases which have been studied show that the large hepatic trunks may be invaded by active inflammatory processes in the liver, such as metastatic abscesses; also, inflammation of the peritoneum and pericardium may invade the cava and ostia of the hepatic trunks; it may result from primary inflammatory processes in the cava and trunks of the hepatic veins; obstruction of the hepatic trunks may also occur from primary thrombotic

processes within the veins, and this may occur when there is no evidence of any primary inflammatory process in the cava or hepatic veins or the peritoneum or Glisson's capsule.

LITERATURE

The first case reported was by Budd,¹ who reported two instances of obstruction of the hepatic veins which attended hepatic abscess, and one case of obstruction of the hepatic veins which was associated with synechia cordis, perihepatitis and peritonitis.

About the same time Frerichs² reported what he described as phlebitis hepatica adhesiva. He says: "This is on the whole a rare form of inflammation and in most cases results from inflammation of the capsule of the liver and coriaceous covering of the diaphragm at the posterior margin of the liver, which is projected into the vein. The wall of the vein becomes thickened, whilst gelatinous deposits and occasional valvular projections, narrowing the channel of the vessels and sometimes completely obliterating some of the branches, will develop on the internal surface. This condition is attended by symptoms of obstruction similar to those which result from occlusion of the portal vein, with the addition of extravasations of blood into the hepatic tissue. Thrombi are liable to develop in the portal vein on account of obstructed circulation."

Frerichs concluded his necropsy observations on this case with the statement that clinical differentiation between obliteration of the hepatic veins and obstruction of the portal vein is impossible.

A case of complete obliteration of the mouths of the hepatic veins has been reported.³ A child, aged 17 months, three months before death showed evidences of a painful swelling of the abdomen. There was no jaundice and no hemorrhage. When the child was 16 months old, two months after the onset of illness and one month before death, the abdomen was tapped and 12 ounces of greenish serum were withdrawn which had a specific gravity of 1.011. Nineteen days after the first tapping, the second tapping was done and 2 pints of fluid withdrawn. Death occurred in five days after the second tapping. Although there is a statement that there was no peritoneal inflammation and that the liver, which weighed 16¾ ounces, was probably smaller than it should be and increased in density with rounded edges, nevertheless the capsule of the liver was everywhere thickened, especially about the suspensory ligament and half of the left lobe, and Glisson's capsule was much thickened in the portal fissure. Section revealed a nutmeg character to the liver. The hepatic lobules had a dark center, surrounded by a fatty zone. Tracing the hepatic veins toward the vena cava, they were found to end abruptly just short of entering the cava, and were cut off from the cava by a thin membrane. The lining of the cava was perfectly smooth and normal. Where the mouths of the hepatic veins should have been, there were shallow dimples, which had not at all the look of scars. Many of the large branches of the hepatic veins were filled by colorless adherent thrombi.

Eppinger⁴ reported a case of obstruction of the intrahepatic portion of the cava with thrombosis of the hepatic veins and diffuse interstitial hepatitis, which was interpreted as syphilitic.

From Quincke's clinic at Kiel, 1886, William Lange reported a case.

From the same clinic in 1899, J. H. Thran reported the case of a woman, aged 32, who entered the Frauenklinik in August, 1897, where an exploratory incision was made. The liver was not enlarged, but the spleen was slightly enlarged and there was a large ascitic accumulation. Four months later she entered the medical clinic on account of an enormous ascites. It was there observed that the right lobe of the liver was not enlarged but was hard and granular. The left lobe of the liver was, however, increased in size, and the spleen was at the costal border. At necropsy the

liver weighed 1,760 gm. and the spleen weighed 550. There was thrombosis of the cava just below the entrance of the hepatic veins. The large trunks of the hepatic veins were obstructed by fresh thrombi. The portal vein and hepatic artery were normal.

Churton⁵ reported the case of a man, aged 26, who died after a short residence in the hospital. The case was interpreted as hydatid cyst, but turned out at necropsy to be due to serous fluid, which was fixed between the liver and the diaphragm. In the center of a cirrhotic liver was found a hepatic vein with an organized thrombus. Churton says the histologic appearance suggested that fibrous tissue had invaded the hepatic vein from the outside. There were no evidences of involvement of the cava.

In 1899 Chiari⁶ of Prague reported three cases under the title of "Obliterating Phlebitis of the Large Trunks of the Hepatic Veins as a Cause of Death." In reviewing older literature, Chiari makes the statement that obliterating phlebitis of the large hepatic veins had been interpreted as evidence of a process of contiguity, and supposedly originated from inflammatory processes in the vicinity of the hepatic veins. But he reports three cases in which the necropsy revealed a primary obliterating phlebitis of the hepatic veins.

The first case, seen in 1885, concerned a woman, aged 28, who was serving as a wet nurse. The patient died at the end of a three days' illness, which began with very stormy symptoms of abdominal pain, nausea and vomiting. The sudden onset of the illness and the obscurity of the symptoms led to a medicolegal investigation on account of the suspicion of poisoning. The severe symptoms in this patient lasted only fourteen hours before death occurred.

The interpretation of this case was that the patient had a moderate amount of stasis due to syphilitic phlebitis, which had existed for a long time; but the acute symptoms which developed a few days before death were due to complete occlusion of the hepatic veins by the formation of fresh thrombi.

Chiari's second case came to necropsy in 1893. The patient was ill for several months and developed the clinical signs of ascites attended with pain which suggested peritonitis. Three and five-tenths liters of bloody serum were found in the peritoneal cavity. There was an aneurysm of the left ventricle of the heart the size of a hen's egg, which was traceable to an obliterating arteritis of the left coronary artery. The liver was slightly enlarged; the capsule was not thickened; the veins were full of blood and there were thrombi in the portal vein. At the openings of the hepatic veins into the cava there was scar tissue which completely obstructed the lumen of the veins.

Chiari's third patient, a man, aged 29, was examined at necropsy in 1895. This patient showed symptoms for three months prior to his death. There was rapid enlargement of the liver, enlargement of the spleen, and ascites. Six liters were withdrawn from the abdomen shortly after entering the hospital. Two days later another paracentesis was performed, and 10 liters were withdrawn. Five days later the patient died. The patient gave the history of gonococcus infection, but denied syphilis, and prior to his terminal illness had never been sick. A clinical diagnosis was made of hepatic cirrhosis, ascites and hydrothorax. When the abdomen was opened at necropsy, 10 liters of hemorrhagic serum were removed. The left pleural cavity contained about 50 c.c. of hemorrhagic serum. Following the hepatic veins to their ostia, it was found that their walls were greatly thickened. At the point where they opened into the cava, the lumina were so narrow that an anatomic sound could scarcely be passed.

Hess⁷ reports the case of a girl, aged 16, who at 12 years of age was admitted to the Prague hospital with ascites, from which she recovered and lived four years before the ascites returned. After the return of ascites, death followed very rapidly. Hess says this was clearly due to a growth of the intima of the cava encroaching on the intima of the hepatic veins at their ostia. The cava and hepatic veins

were both involved. There was no evidence of syphilis, nor was there any evidence of the process being secondary to perihepatitis.

Umbreit⁸ reports a case in which he found no primary phlebitis but a chronic thrombotic process in the radicles of the large hepatic veins, and these thrombi gradually extended to the large branches of the hepatic veins. This was a purely intrahepatic disease, and could not be well accounted for by syphilis, as the process was purely thrombotic and not phlebitic.

Sternberg⁹ reports a case in which the patient had a history of illness for six months prior to death. There was stenosis of the cava in its intrahepatic portion, and thrombi of the hepatic veins. The hepatic veins at their ostia, however, were intact. The cava process and the hepatic vein process seemed to be independently developed; it was purely a thrombotic process within the large trunks of the hepatic veins, and Sternberg suggests that the process could have been infectious in origin and may have originated from a preceding influenzal infection.

Issel¹⁰ found thrombi in the large hepatic veins, which gave the same picture as in Umbreit's cases. The process was interpreted as being purely thrombotic, and not a primary phlebitis with secondary formation of thrombi. The openings of the veins and cava were normal.

Rendu and Poulain¹¹ report a case in which the liver weighed 1,200 gm. There was slight thickening in Glisson's capsule. There was no pronounced perihepatitis, however, or synechia at any point. The portal veins and cava were normal. There was nothing visible to account for portal stasis. It was only on histologic examination that organized thrombi were found in the hepatic veins which involved nearly four fifths of the liver. In this case gross examination was not satisfactory, but the histologic examination revealed a disease of the hepatic veins.

Nagayo¹² describes four cases, two with and two without cava obstruction. All the cases were diagnosed clinically as cirrhosis of the liver and cirrhosis with peritonitis.

A few years later, Nishikawa¹³ published a report of ten cases of obstruction of the hepatic veins. Among these ten are the four cases reported by Nagayo in 1910, and two reported by Yamagiwa¹⁴ in 1905.

The first case that Nishikawa reports is of a man, aged 51, who died after four days' residence in the hospital. He complained of pressure and pain in the right upper abdomen, and 6 liters of blood-tinged, straw-colored fluid were removed by paracentesis. The necropsy disclosed complete closure of the abdominal cava directly below the conflux of the liver veins with the cava, marked stenosis of the large hepatic veins, and complete occlusion of the other hepatic veins. There was great enlargement and cirrhosis of the liver from stasis in the left lobe of the liver, and pronounced atrophy of the right lobe, so that it consisted of a fibrous mass and was a mere appendage to the enlarged left lobe. There were also ascites, edema of the trunk and lower extremities, typical stasis of the spleen, diffuse fibrous union between the liver and the right kidney, and obsolete pleurisy of the right side. Only a brief history of the last illness of this man could be procured.

The second patient had an adhesive pericarditis, but the statement is made that no demonstrable relation between the old pericardial lesion and obstruction of the cava and hepatic veins could be detected. This patient had also obstruction of the portal veins as well.

The third patient, aged 31, was examined at necropsy in 1914. During the clinical observation of this patient, it was observed that he had marked dilatation of the abdominal veins, and although on entrance to the hospital he had marked edema of the lower extremities, it had entirely dis-

appeared. After a few weeks' residence in the hospital, the patient vomited a large amount of blood. More hematemesis occurred three days later, and death three days after the last vomiting of blood. In this case the clinical diagnosis of obliteration of the inferior vena cava and hepatic veins was made. At necropsy, complete obliteration of the inferior vena cava was found as it passes through the diaphragm, and there was obstruction of the large hepatic veins at their entrance to the cava, marked stasis, cirrhosis of the liver with hepatic adhesions, and multiple rupture of varicose esophageal veins.

The fourth patient was a man, aged 26, whose illness began when he was 15 years old. At that time he had marked protrusion of the epigastrium, great impairment in the appetite, and was very intolerant of cold. When he was 23 years of age he had gastro-intestinal disturbances, diarrhea and some fever. Following this there developed a pleurisy of the right side, from which he recovered in two months. At that time an enlargement of the spleen was observed. Two years before his death there was marked edema of the legs, which, however, disappeared after a few days. Four years prior to his death he had a syphilitic infection. When this patient entered the clinic, the subcutaneous veins in the anterior abdominal wall were dilated. The thoraco-epigastric veins and median xiphoid veins were varicose. The current was from below upward. Abdominal paracentesis was performed eleven times. The fluid was on some occasions chylous and hemorrhagic, and at other times straw colored and slightly turbid.

The fifth patient, a woman, aged 34, was examined at necropsy in January, 1915. When she was only 10 years old, a diagnosis was made of hepatic disease. Eight years before death, marked dilatation of the subcutaneous veins of the abdomen was observed, and two years before death there was marked swelling of the abdomen, which did not subside and which led to paracentesis. The fluid was yellow and slightly turbid. The liver was then found about three finger breadths below the costal borders and had a rough surface and firm edge. Three months later, paracentesis was again performed, and 2.5 liters were removed. Paracentesis was performed again after three months. A month later, death occurred. In this instance a clinical diagnosis of obstruction of the intrahepatic portion of the cava was made. Necropsy revealed obliteration of all the hepatic veins at their opening into the cava, marked stenosis of the vena cava as it passed through the diaphragm, and stasis cirrhosis of the liver.

The sixth patient was a man, aged 39, who had syphilis when he was 21, and two years later suffered from anorexia, vomiting and pain in the epigastrium. At that time he noticed dilatation of the abdominal veins. Two years before death, he noticed protrusion of the abdomen, and later edema of the lower extremities. Six months before death he entered the hospital. At that time there was no ascites and the liver was not palpable. There was no clinical diagnosis reported in this case. However, the necropsy revealed obliteration of the inferior cava as it emerges through the diaphragm.

The seventh patient, a woman, aged 30, examined at necropsy in July, 1913, had noticed two years before death moderate distention of the epigastrium, and two months before death there was edema of the lower extremities and distention of the whole epigastrium. She was never icteric, but had hematemesis on several occasions. There was also some blood in the stools, and the urine contained some urobilin but no bile pigment. Paracentesis was performed four times. A clear, yellow fluid was procured each time. The Wassermann reaction was negative. A clinical diagnosis of cirrhosis of the liver was made. Necropsy revealed complete obliteration of all liver veins emptying into the cava, marked stenosis of the vena cava below the entrance to the hepatic veins, a high degree of stasis cirrhosis of the liver, adhesions between the lower surface of the liver and the ascending colon, and diffuse adhesive pleurisy of the left side. The liver weighed 1,650 gm.; the whole organ was firm and finely granular. The cut surface showed a typical picture of stasis cirrhosis. The statement is made that there was no evidence of syphilis at the necropsy.

The eighth patient, a woman, aged 38, examined at necropsy in 1910, a year and a half before death had accidentally discovered a painless tumor in the right hypochondrium the size of a pigeon's egg. The tumor gradually increased in size, and about eight weeks before death she noticed pain in the epigastrium and loss of appetite. She was treated at home for tumor of the stomach. One month before death she entered the hospital. She was a small woman, with dry skin, no edema, and slightly icteric hue of the sclera. The liver was palpable three finger breadths above the umbilicus in the median line. The left lobe was particularly hard; the surface was uniform and granular. There was a tumor in the right lobe of the liver. The spleen was palpable, firm and not painful. The clinical diagnosis was made of carcinoma of the liver. Carcinoma of the stomach was apparently eliminated on account of the presence of hydrochloric acid, pepsin and lab-ferment, and the want of lactic acid in the stomach contents. The necropsy revealed a complete obliteration of the large liver veins at their entrance to the cava. Just below the entrance of the liver veins, the cava was almost completely obstructed by membranous thrombi.

The ninth patient, a woman, aged 32, observed the first symptoms in March, 1908, and she died, Aug. 30, 1909. In March, 1908, she observed edema of the legs, which increased with standing. At that time her appetite was good, but after eating she suffered from a sense of pressure in the epigastrium. At the same time the patient observed a hard tumor in the region of the liver, which was not sensitive. In May, 1909, the patient noticed distention of the abdomen and dilatation of the subcutaneous veins in the anterior abdominal wall. There were occasional remissions of this abdominal swelling, and suddenly, about the beginning of August, 1909, the abdominal distention greatly increased. She was admitted to the hospital only ten days before death. There was general anasarca, and the abdomen was greatly distended with fluid. Nine days before death, 8,750 c.c. of fluid were removed from the abdomen and proved to be a transudate. After paracentesis the liver was palpable about a finger breadth below the costal margin. The edge of the liver was hard. The clinical diagnosis was hepatic cirrhosis. Necropsy revealed obliterating phlebitis of all hepatic veins at their entrance to the cava.

The tenth patient, a man, aged 28, examined at necropsy in October, 1908, had noticed dilatation of the superficial veins of the trunk when 15 years of age. At 24 years of age the dilatation of the epigastric veins was notably increased. The abdomen was much distended, when the patient entered the hospital one month before death. During the month's stay in hospital, four paracenteses were performed, and each time about 6 liters of transudate were removed. The liver and spleen were not palpable. The liver in this case was not enlarged. It was irregular and grossly nodular. There were numerous nodules the size of an egg, which were interpreted as indicating primary carcinoma of the liver. The portal vein was completely filled with gray-red thrombi. All the hepatic veins were completely obstructed by organized thrombi at their entrance to the cava, and the cava was completely obliterated below the entrance of the hepatic veins.

SUMMARY AND CONCLUSIONS

Thirty cases of obstruction of the hepatic veins have been reported in accessible medical literature since the time of Budd in 1857.

Ten cases, or one third of all, are reported in a monograph by Nishikawa from Tokyo University, and they were all observed in the ten years from 1905 to 1915.

In the reports of Nishikawa's cases it is quite apparent that if the intrahepatic cava and ostia of the hepatic veins had not been examined as a routine measure, the ascites from portal stasis could have been explained by some other attending causes to the satisfaction of less critical pathologists. Nearly all his cases were attended with some lesion associated with ascites, namely, syphilis, cirrhosis, carcinoma,

perihepatitis, thrombi of the portal veins or tuberculosis. These are all enumerated as lesions that were present, and yet either thrombophlebitis or primary thromboses of the hepatic veins were the sole causes of ascites in all of Nishikawa's cases.

The other lesions were incidental in some instances, and probably in other cases played a contributing part to production of hepatic vein lesions.

In only two of all reported cases was the diagnosis of obstruction of the hepatic veins made before death. All the other diagnoses were made at necropsy. Several writers suggest that the clinical diagnosis should be made, and others say the lesion is purely a pathologic curiosity which cannot be differentiated from obstructive lesions in the branches or trunk of the portal veins.

The affluent blood flow of the liver consists, 70 per cent. of portal blood, and 30 per cent. of blood from the hepatic artery. The total efferent flow is through the hepatic veins. There is a free anastomosis between the bed of the hepatic artery and the bed of the portal vein. Should obstruction occur in the trunks of the hepatic veins, the pressure within the entire capillary system of the liver will arise not only from pressure in the portal vein but also from the hepatic artery, whose branches anastomose freely with those of the portal vein.

The result of such obstruction will cause great distention of Glisson's capsule.

The convexity of the upper surface of the liver is increased, the edge is rounded, and the resistance of the liver is greatly increased. The bursting tension on Glisson's capsule is very great, on account of the liver's large diameter. Bursting tension is equal to the pressure multiplied by the diameter, so in this case there is ample source for sensitiveness to pressure from an examining hand. The cases seen at necropsy show that auxiliary veins opening into the cava will readily give some relief to the high capillary pressure, and so will the anastomotic veins offer new efferent paths, as occurs in portal obstruction.

Should obstruction of the portal vein occur, there will be a diminution in size of the liver. Enlargement of the liver accompanied by ascites cannot be caused by heightened resistance to blood flow from lesions in the portal veins. If there is obstruction in both hepatic veins and portal veins, then the liver will not be enlarged; but ascites follows from stasis in the portal radicles.

When the hepatic veins are obstructed, the clinical signs are essentially: acute enlargement of the liver; convex upper surface; increased resistance; rounded edge and pain on pressure, and an ascitic transudate which is opalescent and contains numerous red cells with few white cells and does not readily clot on standing. The specific gravity of the transudate ranges between 1.004 and 1.014. These are the positive signs; but the want of any evidence of disease of the hepatic parenchyma is also important. There is neither choluria nor cholemia, and urobilin is not increased in the urine. The two cases discussed which have been under observation for the last year have at no time had an icteric plasma, and a notable feature of the other cases reported was the want of any icterus of the skin or bilirubin in the urine. In fact, every contributor on the subject comments on this absence of icterus of the skin and of bile from the urine. It is doubtful whether such acute and pronounced

enlargements of the liver due to parenchymatous and interstitial disease could occur without constant or at least intermittent icterus of the plasma, even should there be no bile in the urine or visible jaundice of the skin.

If all sources of hepatic enlargement with the exception of venous stasis can be eliminated, the problem remains to determine whether hepatic stasis originates from cardiac insufficiency, obstruction of the inferior cava above the ostia of the hepatic veins, or obstruction of the hepatic veins.

The possibility of a cardiac source must be disposed of by the usual methods employed in estimating the size and functional capacity of the heart.

Involvement of the cava with hepatic vein obstruction reveals an association between these two lesions which requires further elucidation of the mechanism by which the two paths are obstructed. With stenosis of the inferior cava above the hepatic vein there will follow exactly the same symptoms in the liver that occur in stenosis of the hepatic veins, and in addition there will be signs of obstruction of the cava. In four of Nishikawa's ten reported cases there was obstruction of the cava where it pierces the diaphragm. In the tenth case there was stenosis of the cava both above and below the opening of the hepatic veins. In five of his ten cases, the cava was narrowed only below the hepatic veins. In only one case of the Japanese reports were the hepatic veins open, and in that case (the fourth of the report) the lumen of the cava was narrowed to 1 mm. above the entrance of the hepatic veins.

In all ten cases there was stenosis of the cava, and in only one instance were the hepatic veins unobstructed.

In some of the cases reported from other sources the hepatic veins were not examined until after the liver had been removed, and in other reports the account of the cava is not sufficiently clear to inform us whether there was an adequate examination of the cava and its lumen.

About half of the reports prior to the Japanese publication give definite accounts of narrowing of the cava by either old or recent thrombi. There is certainly a definite interdependence between the two lesions.

The relation may be direct extension from inflammation of the cava wall into the walls of the hepatic veins, as described in two of Chiari's cases and in the case reported by Hess; but in other instances there has been no demonstrable phlebitis or even endophlebitis. There was a deposit of riffled thrombi composed of red and white cells and fibrin. Aschoff¹⁵ gives an interesting discussion on the manner in which agglutinated red cells, leukocytes, bacteria and fibrin may be deposited on the intima of veins in the vicinity of stenosis, or in widening of the vascular lumen and also near the point of confluence of a lesser stream and slower velocity of current with a larger stream and swifter current. All these physical conditions contribute to formation of eddies, which are currents moving contrary to the main current and usually in a circular direction. There may be two eddies moving circularly but in opposite directions, and it is opposite the points of friction between the surfaces of these contrarily moving eddies that the riffled thrombi are deposited. The intrahepatic por-

tion of the cava is a location very favorable for the production of eddies.

The cava here widens into a considerable bulbus into which open the mouths of the hepatic veins. There is then a wide lumen into which open a number of lesser lumina, and the velocity of the confluent currents is subject to great variations from breathing, coughing and rotation of the liver on a transverse axis, which is located by the posterior border of the liver that is not covered by peritoneum.

Not all the factors that contribute to formation of these thrombi are clear; but it seems that the causes mentioned above may share in the deposit of thrombi in the hepatic veins and in the cava when there is no basis for thrombus formation on account of disease of the venous walls.

This mechanism of thrombus formation seems very reasonable in view of the number of cases reported in which thrombi of the hepatic veins were located at the mouths of the veins or within a centimeter of their openings into the cava. When the intrahepatic cava was opened, the sites of the ostia of the hepatic veins were indicated by so many dimples on the hepatic aspect of the cava. In a few cases the thrombi were located at some distance from the ostia of the veins when the process was purely thrombotic and unaccompanied by evidence of endophlebitis.

Even in those cases, like Chiari's, in which there was severe inflammation of the cava and veins, the sudden precipitation of symptoms and rapidly fatal course may be traceable to the mechanism of eddies in the blood current which produced the fatal thrombi in both the cava and at the ostia of the hepatic veins.

The clinical course of hepatic vein obstruction interpreted from necropsy findings and histories of the patients proves that partial obstruction of all the veins or complete obstruction of some of the large veins, may cause acute hepatic symptoms from which partial recovery will follow.

There may remain a regional stasis cirrhosis which will go on to atrophy of all the liver cells in one lobe so that at necropsy (in one case) the entire right hepatic lobe consisted of nothing more than fibrous tissue surrounding the vascular structures. The liver cells had all succumbed, and the right lobe was only a fibrous adnexa to a comparatively well preserved left lobe. There may be enlargement of auxiliary hepatic veins to compensate for obstruction of the original veins; and when portal stasis follows, anastomoses between the portal vein radicles and tributaries to the cava may suffice to produce a long history with varying ascites and the same variety of changes in size, conformation and consistency of the liver that are seen in chronic alcoholic and syphilitic cirrhosis.

The fact that a clinical diagnosis of hepatic cirrhosis was made in most of the cases will indicate the character of the physical signs that are produced by the chronic course of the disease.

The ages of patients ranged from 18 months to advanced life, and the duration of symptoms from three days to thirteen years.

The number of cases of hepatic vein obstruction thus far reported makes it advisable to examine carefully the intrahepatic cava and hepatic veins at the necropsies of all patients who present signs of hepatic disease with ascites.

The collected reports justify the suspicion that, in the past, obstructive lesions of the hepatic veins have

15. Aschoff: Beitr. z. path. Anat. u. z. allg. Path. 52: 205, 1912.

escaped the pathologist's observations on account of failure to make careful examinations of the intra-hepatic cava and its tributaries.

These reports also emphasize the importance of trying to interpret the clinical histories and physical findings in definite relations to disease of the liver cells, interstitial structures and disturbances of blood flow in the portal and hepatic veins and hepatic artery.

ABSTRACT OF DISCUSSION

SIR HUMPHRY ROLLESTON, London, England: Some time ago I analyzed the reported cases, only about thirty, so that, with the eleven which Dr. Hoover has added, there are still less than fifty cases on record. It is, therefore, a curiosity, and not always of the same nature. There may be an acute thrombosis, which was probably the condition in Dr. Hoover's cases. There may be a very remarkable lesion, viz: cicatricial contractions of the orifices of the veins, and this may occur extremely early in life, as in a case of the late Dr. S. Gee. Possibly it is due to an extension of the process of obliteration of the ductus venosus, comparable to the excessive process described by Bland-Sutton as occurring at the site of the duct of Meckel's diverticulum in connection with the small intestine. In some of the cases, as Dr. Hoover has mentioned, syphilis has been given as a cause. Some cases, but by no means all, are associated with obliteration or narrowing of the inferior vena cava in the immediate neighborhood; this may be, as Turnbull and Theodore Thompson suggest, a result of thrombophlebitis, or it may be due to trauma, such as may follow jumping from a considerable height, with the result that a certain amount of tearing occurs either in or underneath the endothelium, where the liver is attached to the inferior vena cava by the hepatic veins, and that from the reparative process, cicatricial contraction follows. I was under the impression that the condition had never been diagnosed correctly. It is true that I have diagnosed it myself, but, as compared with Dr. Hoover, I was doubly unfortunate. In the first place, the patient died, and in the second place, there was not any stenosis of the hepatic veins. Another curious point is the association of well marked stenosis, obviously of long standing, of the orifice of the hepatic veins, with an illness which has only lasted a short time—a few weeks. It looks, indeed, as if the slow current through the hepatic veins was sufficient until, perhaps, as a result of some terminal thrombosis, the orifices were almost or completely obstructed, when complete insufficiency of the liver took place, with an acute onset of symptoms.

DR. FRANK B. WYNN, Indianapolis: About four years ago I saw a case of phlebitis involving the lower limb on the right side, first, then passed to the left side. Under rest, the patient slowly recovered, except for slight edema of the leg incident to the venous obstruction following the thrombophlebitis. Four months later he developed a phlebitis of the veins in the side of the chest, which under rest gradually improved. But, again, after about two months, he returned with what he thought was an acute indigestion. One night he had an attack of excruciating pain, requiring a hypodermic. The pain was referred to the region of the gallbladder. It was so excruciating that he broke out with a clammy sweat. A surgeon called in consultation considered it a gallbladder lesion. In a few hours swelling had occurred in the hepatic and epigastric areas. Six hours later the man was seized with vomiting of dark blood, which continued until he died, four or five hours afterward. The necropsy revealed some of the things which have been described by Dr. Hoover, and some additional ones; namely, that he had had one after another, attacks of phlebitis, first in the legs, and then in the different veins, with the last attack in the cavæ and hepatic veins. But the dominant feature, pathologically speaking, was the extensive thrombophlebitis of the portal vein. His intestine was entirely filled with dark blood, and his stomach was also full of

blood. The liver was greatly swollen, and the hepatic veins were distended.

DR. CHARLES F. HOOVER, Cleveland: Dr. Wynn's case probably involved tributaries to the vena cava as well as tributaries to the portal vein. It is very surprising to find that patients with complete obstruction of the cava below the openings of the hepatic veins rarely show severe evidences of stasis, and in many instances there is no edema and no dilatation of visible veins to indicate the obstruction. In fact, with few exceptions, the obstruction of the cava is only suspected, and the evidence of symptoms having existed at any time is elicited only on carefully questioning the patient. The histories of these patients have extended all the way from a few days to thirteen years. In many instances a partial restoration of the lumen of the hepatic veins and the enlargement of accessory hepatic veins have sufficed to allay symptoms for as long as four or five years. The two patients I have had are still living; therefore, the pathologic proof of the lesion is wanting. Had I not seen the first patient in his acute attack, I am sure the case would have been passed without question as one of hepatic cirrhosis.

A STUDY OF THE BILE PIGMENTS IN PERNICIOUS ANEMIA*

J. P. SCHNEIDER, M.D.

MINNEAPOLIS

In 1916 I described¹ a spectroscopic method for measuring the bile pigments, urobilin and urobilinogen, secured with the ordinary Einhorn duodenal tube in the fasting patient. I asserted for the method simplicity, reliability and reasonable accuracy. After five years of experience, embracing several hundred determinations, I can report no serious defects in the method, nor have I seen in the literature any valid criticisms. Krumbhaar² points out apparent wide fluctuations in the urobilin content of bile found by Wilbur and Addis. That wide variations are not found can be readily demonstrated by securing duodenal contents in healthy student material. This is shown in Table 1. Variations such as obtain in all the gastro-intestinal secretions is to be expected, and for clinical purposes these do not vitiate the test. Moreover, the stool method is subject to precisely the same variation plus the added errors of variable resorption by the intestine, to say nothing of the disappearance of a fraction of these very unstable pigments through the action of an inconstant intestinal flora. Of prime significance is the detection of urobilinogen in the duodenal contents, for this pigment is never present in health. Krumbhaar's final objection that the method is more liable to errors in the collection of material than the stool method is certainly true in the hands of the inexperienced, but here again several removals may be made on the same patient for control, in less time and with far less labor than is consumed by a forty-eight hour stool determination.

Lyon³ apparently has neglected to establish the values of bilirubin and urobilin as they obtain in the fasting healthy individual, for he says: "When bile is

found in the fasting duodenum in sufficient quantities to be grossly visible we believe that there is either a disturbed physiologic condition or a pathologic lesion of group organs physiologically related to this intestinal zone." A little experience with healthy student material would have obviated this totally erroneous assumption. Hansmann and Howard⁴ used the duodenal method in five cases of pernicious anemia. "Three showed the abnormal presence of urobilinogen, which amounted to 6,800, 2,400 and 1,520 dilutions, respectively; the other two cases which were negative were undoubtedly cases of pernicious anemia, and there was a well defined increase of the urobilinogen in the stools. We have therefore placed less confidence in the duodenal determination than in that of the urine and stools, contrary to our expectation entertained after reading Schneider's and Giffin's articles. It is, of course, possible that more experience in the method might overcome our present prejudice." Since these workers give no evidence of having first at least reasonably perfected their technic of securing duodenal contents, and at the same time state that in the two cases in which they missed the pathologic increase

dilution at a dissimilar rate; therefore the number of dilutions may not be added. With this explanation it is to be taken that the total pigment values of urobilin and urobilinogen are so grouped merely for comparative purposes. The quantitative estimation of bilirubin by the Huppert method leaves so much to be desired that the values are indicated but roughly.

In the securing of the duodenal sample it is not uncommon, if the patient retches a good deal, to have bile mixed with gastric secretion issue from the tube when the bulb is still in the stomach. When there is an absence of free hydrochloric acid the contents may be alkaline to litmus, and the inexperienced worker will take this diluted material for genuine duodenal secretion and naturally find lower readings. To obviate this error it is necessary, if the patient has been nauseated by the introduction of the tube, to give an added allowance of time for this regurgitated material to be siphoned off and for the bucket to pass over into the duodenum, when by comparison a much stronger alkaline reacting secretion will be found, and a gentle tug at the tube by the operator will be resisted by the

of pigments in the supposed duodenal contents they found abnormal urobilinogen stool content, it is safe to assume that they failed to enter the duodenum. Among the workers who have used the method extensively there stand out Giffin, Sanford and Szlapka.⁵ They report a total of 119 tests in eighty-nine cases, sixty-one of which were patients afflicted with pernicious anemia. They thus report their experience:

The values obtained by the author's method have been so definitely in accord with the clinical manifestations that there is little doubt of the existence of a relationship which it is to be hoped may be made clearer by further study. These values are also in accord with the results obtained from estimations on the stool. . . . In pernicious anemia the amounts of urobilin and urobilinogen in the duodenal contents were above normal in 84 per cent. of the cases. The amount of urobilinogen was constantly increased when the anemia was severe.

It is necessary to explain that the total of urobilin and urobilinogen as estimated by the spectroscopic technic is not intended to be chemically correct. The absorption bands of these two pigments disappear on

bucket if it be beyond the sphincter. When free acid is present in the stomach this error is not likely to happen. However, all of the refinements in the technic of securing the material, which I originally described, should be painstakingly followed.

In my experience the most difficult cases have been those in which the spleens were very large. In a number of these it was impossible to get the bucket into the duodenum. In one I succeeded by allowing the tube to remain in situ for twenty-four hours.

In order to reestablish the truth of my contention that urobilin does not occur in the duodenal secretion as obtained by the Einhorn tube in the normal fasting adult in amounts exceeding 1,000 units, that urobilinogen is never present in health, and that diet has no immediate influence on the values of either, I had a series of twenty-three removals made on volunteer students, the results of which appear in Table 1. Incidentally, it occurred to me, acting on a suggestion derived from the work of Barratt and Yorke,⁶ to investigate in a small way the effect on these pigments of quinin sulphate. Relative to the first contention, it is obvious that, regardless of diet, the lowest value of urobilin found was 400 units, the highest 800, that

urobilinogen occurred only once, and that in a student, the third day of a lacunar tonsillitis. In this, as in other bacterial invasions, such as scarlet fever, there is every reason to suspect acute parenchymatous hepatitis. It is to be particularly noted that the liver disturbance affects urobilinogen and not urobilin, the value of which is normal. Severe constipation induced by tincture of opium did not affect the value of either pigment.

still high thirteen days later. Four days later a control test gave normal values. While urobilinogen was always found, urobilin values were particularly high, suggesting the relative values found in hemolytic states. It is not improbable that quinin has hemolytic properties, and those who contend that the hemoglobinuria occurring in certain malarialized districts is due to the ingestion of quinin may be shown eventually to be correct in their belief. Work is now in progress

Relative to the effect on the values of these two pigments particularly, of from 60 to 75 grains of quinin sulphate administered by mouth in the preceding forty-eight hours, the table tells a rather striking story. In each of the eight instances a pathologic pigment level was found. In two instances the same student was used a second time with a similar result. In one instance in which the student complained of a persistence of ringing in his ears, the pigments were

with the end in view of determining whether quinin acts on the red cell directly or on the liver or spleen parenchyma.

From October, 1915, to March, 1920, a total of 104 patients ill with pernicious anemia was seen and rather completely studied. Of these, seventy-eight have sufficiently complete records to allow of tabulating (Tables 2, 3 and 4) for the years 1915-1916, 1917-1918 and 1919-1920, respectively. In these seventy-

eight cases there were repeated bile examinations in a considerable number, so that the total number of duodenal removals is 120. Only one determination is given in the tables for each patient, and when there were more, the duodenal test nearest to the blood examination in point of time was selected. (Frequently both were done the same day.)

normal pigment values, two of which were repeated with the same result. One is dead, two are living. Two are certainly cases of pernicious anemia; in the other there are still a few elements of doubt.

An indication of the fatal character of this disease is the fact that of seventy-five patients traced, fifty-two are dead. Of the 1915-1916 series only one, and that

Of the seventy-eight patients, forty-one were men and thirty-seven were women. The average age was 45 years. The oldest patient was 66, the youngest, 18. The average number of months the patient had been ill when first seen was fifteen. The average total length of illness of those who died was 2.6 years, the shortest being six months and the longest six and one-half years. The average red blood cell count was

TABLE 5.—RELATION OF MARROW TO SPLEEN-LIVER

2,000,000 per cubic millimeter. The average hemoglobin (Sahli, corrected, and Dare) was 40 per cent. The average hemoglobin index was 1 and the average white blood cell count 4,400. The degree of cord involvement was: twenty, severe; twenty, moderate; twenty, slight; eighteen, none. The average total bile pigments (urobilin and urobilinogen) was 3,330 units, the highest total being 6,800, and the lowest 800. Three patients out of the total (Cases 34, 54 and 77) gave

a splenectomized patient, is living. Of the 1917-1918 series, fourteen are dead and twelve living. Of the 1919-1920 series, eleven are dead and ten living.

In 1917⁷ I proposed a simple formula by means of which it might be possible to express the relation of blood regeneration to blood destruction in a given instance. For short this hematopoietic-hemolytic relationship is designated as the H-H index. Normally this is 1. When hemolysis is very active it will tend to be plus, and when hemopoiesis fails it will fall below 1.

If our concept that early in pernicious anemia the hemolytic factor is uppermost and that later in the life history of the disease the marrow fails is true, then the H-H index should be higher in the early cases. In our series the H-H index of all who gave a history of twelve months or less of illness is 1.16 (disregarding Cases 34, 54 and 77). The H-H index of all who were ill more than twelve months is 0.83. If Cases 34, 54 and 77 are included, those of twelve months or less standing yield an H-H index average of 0.86. The early cases have a higher average red blood cell count, the highest being 4,200,000. The average H-H index in all having a red cell count of 2,000,000 or over—namely, thirty-eight cases, including Cases 54 and 77, is 0.95. The average H-H index of the forty cases with a count under 2,000,000 is 0.78.

If we are correct in our concept relative to the meaning of a low H-H index, then the degree of leukopenia should run more or less parallel with it. In twenty-four of the seventy-eight cases the total white blood cell count was 5,000 or over, and here the average H-H index is 0.95. In fifty-four of the seventy-eight cases the leukocyte count was less than 5,000, and in these the average H-H index is 0.83. To my mind this fact is highly confirmatory of a previous statement in which I indicated that a low H-H index

7. Schneider, J. P.: Further Quantitative Study of the Duodenal Blood-Derived Pigments, Arch. Int. Med. 19: 156-162 (Jan.) 1917.

taken with a leukopenia, however short the illness in point of time, indicated a bad prognosis. Table 5 schematically represents the marrow-spleen-liver relationship, and the resulting H-H index in the normal, aplastic anemia, late pernicious, early pernicious, and hemolytic icterus.

In a recent editorial⁸ in *THE JOURNAL* commenting on the work of Rous and Oliver occur these sentences: "The diagnosis of diseases like pernicious anemia and hemochromatosis involving a hemosiderosis has sometimes been extremely difficult, unless a conspicuous siderosis of the skin has developed. Necropsy usually reveals far more siderosis in the internal organs, but it cannot be detected during life." Table 6⁹ summarizes the pigment findings at necropsy in seventeen patients dying of pernicious anemia. Six of these are represented in our series, and presented high duodenal values. In Case 76, O. W., there was no clinical evidence of pigment accumulation, nor was there hematologic evidence for pernicious anemia.

* In this column, ♂ indicates male and ♀, female.

The only suggestive findings were neurologic. The bile study, with values of 4,800, 4,600 and 4,800 units on three separate occasions, was the decisive finding in the case. I would therefore say that siderosis can be detected during life.

414 Syndicate Building.

ABSTRACT OF DISCUSSION

DR. LEONARD G. ROWNTREE, Minneapolis: For two or three years prior to going to Minnesota I was interested in the development of functional tests for the liver. We made a large number of determinations of urobilinogen in relation to liver diseases. During the course of this work, Wilbur and Addis reported their results, showing the tremendous variations which they encountered. We never published the results of these experiments because the variations were tremendous. When I came to Minnesota, I was not in a particularly receptive frame of mind for these studies which Dr. Schneider reported. I saw his work. I saw cases of pernicious anemia followed after splenectomy and after transfusion. In some cases fifteen or twenty determinations were made on the same patient, and always I saw these

constant high values for the bile pigments. I could not help but become converted to a belief in the value of his methods. They deserve much greater attention than they have received. Dr. Schneider's quinin experiments are of interest. Quinin is absorbed from the intestine, is held in the red blood cells, and most of it is destroyed in the body. Some of it is excreted in very small quantities in the urine, the milk and other secretions. It is interesting to note that blackwater fever has followed the use of quinin in pernicious anemia. Of course, in malaria blackwater fever occurs with and without the use of quinin. With the storage of quinin in the blood cells and the hemorrhagic influence on the part of the plasmodium, it is more than probable that some causal relationship exists between quinin and blackwater fever. The greatest need in the study of diseases of the blood and of the liver at present is a more exact chemical knowledge of both the bile and the blood pigments.

DR. G. J. HIRSCHBOECK, Duluth, Minn.: We have used this test rather frequently since Dr. Schneider first initiated its use, and we were rather forcibly impressed at the beginning with its value in the differential diagnosis of obscure

conditions. In a case of beginning carcinoma of the stomach, in which the findings were not by any means definite, the patient's nutrition was good, but he had ulcerative stomatitis and anemia, without any definite blood picture and negative roentgenologic findings. We made the diagnosis of pernicious anemia. The case was referred to Dr. Schneider, who after making his duodenal estimate said that the case was not one of pernicious anemia. The case was followed subsequently, and blood was found in the stools. Later on, typical symptoms developed, the patient was operated on and eventually died, with characteristic postmortem findings of carcinoma of the stomach. The test is also of extreme value in cases of pernicious anemia in which neurologic symptoms predominate, whether only peripheral paresthesias, or as far advanced as a true combined sclerosis. Oftentimes, in these cases, the number of red cells is large and the blood picture is inconclusive, as well. In these cases the test is of great value in differentiating combined sclerosis due to pernicious anemia from those that are not of such origin. It is also of value in cases of syphilis accompanied by anemia. In cases of syphilis, with secondary anemia, in which we find normal pigment values in the duodenum, we obtain improvement by antisyphilitic treatment. Furthermore, in cases with positive serologic findings, and with the typical clinical picture of pernicious anemia if duodenal estimation is performed, if it is found to be low in duodenal pigment units, the spirocheticides improve the cases to cure; and if the units are found to be excessive, antisyphilitic

measures are of no value. This test is not difficult to perform when done frequently, and after the technical difficulties are overcome. It is far less laborious, the amount of time consumed is far less, and it is far more accurate than the stool examination. I would strongly urge its more common adoption and use, because you will find it of immense clinical value in differential diagnosis.

DR. LEWELLYN SALE, St. Louis: The usefulness of a quantitative test, even though it be a rough quantitative estimate of the bile pigments, is realized and admitted. It is not always possible to make use of the duodenal method, as described by Dr. Schneider. I want to call attention to another method, and at the same time, to ask Dr. Schneider if he has made any experiments with this method, in controlling his own, as to its clinical usefulness. This is a quick clinical laboratory estimation of urobilinogen, a rough quantitative estimation by the use of the so-called Ehrlich's reagent, dimethylamidoparabenzaldehyd. Using that reagent in the urine, we were always able to demonstrate the presence of an increased amount of urobilinogen in the urine in cases of increased blood destruction in pernicious anemia, and in other anemias. At the same time, a worker in the same clinic in which we were using this reagent was trying to determine whether or not it might not be of some prognostic value in cases of pulmonary tuberculosis. He claimed that in the more advanced cases, and those which offered a bad prognosis, because of the high degree of toxicity, there was always, even though it was not demonstrable, a certain degree of parenchymatous hepatitis, which could at least be predicated on the presence of an excessive amount of urobilinogen in the urine.

DR. J. P. SCHNEIDER, Minneapolis: To determine pathologic hemolysis, the duodenal technic is the method of choice, with the quantitation stool examination second, largely because of the time element. Urine pigment studies (urobilin and urobilinogen) are utterly valueless in pernicious anemia. They are of signal value in hemolytic icterus and of some differential value in diseases affecting the entire parenchyma of the liver as against obstructive pathology involving the common duct.

THE REPORTING OF VENEREAL DISEASES BY PHYSICIANS*

WILLIAM EDLER, M.D.

Scientific Assistant, United States Public Health Service; Director, Bureau of Venereal Diseases, Louisiana State Board of Health

NEW ORLEANS

Every innovation in medicine has been either preceded or followed by an educational campaign among both the public (the laity) and physicians. Medical progress must be made by acquainting the general public with medical facts. Too long have physicians kept their medical knowledge within their own sphere, expecting the laity to gather their medical education in the stern school of disease experience, leaving the public helpless except for minatory lectures in preventive medicine. The public mind is analogous to the child's mind: Not only must both be told to do a thing, but both demand the whys and wherefores of the thing to be done. Sustained preventive medicine will never come to pass until every child, man and woman knows the immense economic and material reasons for prophylactic medicine.

One can readily understand why a great deal of energy must be expended to acquaint the public with some departure from the routine in medicine. The average person is not presumed to know the needs of

medicine at any given time. But it is difficult to appreciate why the same laborious process must be gone through with physicians. Surely it is expected of them to recognize the demands of the various evolutionary periods that go to make ultimately the history of medicine. Yet it is a fact, and any state health officer will verify the statement, that a great deal of the time of the vital statistics bureau of a state health department is taken up in an attempt to get physicians to write legibly and give reasonable causes for death; or, on the other hand, an expert statistician's time is devoted to doing propaganda work to convince physicians that birth records are a necessity in these modern days of statistical accuracy. In returning death reports to physicians for proper revision, and in a multiplicity of other tasks growing out of the carelessness and negligence of physicians who, in making their reports, do not give the subject the ordinary care that a subject of this kind merits, is the energy and money of this important branch of health activity dissipated.

When we transfer our investigations from the vital statistics bureau to the epidemiology department, the sins of omission and commission increase in a ratio directly proportional to what the physician thinks is an invasion of the rights or privileges of either the patients under his care or of himself.

Only a few years ago it became obligatory on the physician to report tuberculosis as a communicable disease. Despite the law, contrary to all medical knowledge, opposed to the conscientious convictions of the medical practitioner himself, nevertheless an educational campaign had to be conducted among physicians to teach them what they already knew: that tuberculosis is a communicable disease; that there is only one way to control it, and that is for the health officials to know where and to what degree it exists.

State and city boards of health need a law enforcement division for physicians, rather than an educational department. The physician *knows*; he simply does not consider the reporting of communicable diseases a part of his professional duties; and until such time when he is punished for law violations the same as any other individual, until such time as he is impressed with license revocations varying in time with the degree of his offense, not until then will reporting of disease reach any degree of accuracy. One or two prosecutions of this kind in a community, with ample publicity, will produce more communicable disease reports in a week than will years of propaganda.

Recently, in the state of Louisiana, there were found in one small community forty cases of typhoid fever, not one of which had ever been reported. Did any of the physicians attending these cases feel that from a legal and moral standpoint they were criminally liable for this epidemic? Did they feel that they were grossly negligent of a duty they owed their community, their state and the nation? Were they prosecuted? And, above all, will they not do precisely the same thing at some future time?

Much of this sounds like scolding. It is not. It is a frank appeal for state health officers to hold in strict accountability every licensed physician to a trust that the state has imposed on him. A man is readily punished for violation of a traffic ordinance because he endangers the life of a few persons. The physician has under his thumb the lives of whole communities, and he should not be permitted to violate this trust and responsibility.

* Read before the Section on Preventive Medicine and Public Health at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

Laxness and negligence being true in the reporting of those diseases that have been reportable in the past, it can readily be surmised how much more difficult it is to get reports on diseases recently added to the list of communicable diseases. The problem begins to get more complicated when the physician attempts to shield certain classes of his patients; or, in a more mercenary type of physician that is occasionally encountered, when he attempts to enlarge his clientele by circulating among the laity the information that he does not report certain diseases. I refer to the venereal disease triad. I can think of nothing more contemptible than to compete unfairly on such a basis with a fellow practitioner who reports his venereal disease cases. Equally unfair is the physician who thinks he shields wealthy patients by not reporting their venereal disease when, at the same time, he painstakingly reports those not so fortunately situated.

There can be no question that there are physicians who are conscientious objectors to venereal disease reporting. Nevertheless, in this state (Louisiana) they violate the law every time they do not report. Their recourse is in a court of justice. They have no more right to interpret the law, no more justification for violating it, than they have for ignoring any other law. Yet it is only just that an answer should be made to those objections that superficially appear legitimate; and I will discuss them in the order of their importance.

INVALIDITY OF OBJECTIONS TO THE REPORTING OF VENEREAL DISEASES

It is contended that the reporting of venereal diseases in a patient not only violates the individual right of the person to conceal his malady from his fellow man, but also contravenes the established principle of privileged communications between the physician and his patient. This argument has no merit in point of law or in any ethical code. The courts have invariably ruled to the contrary, in the first instance; and our social structure is based on a philosophy diametrically opposed, in the second. No system of government could long endure if it were based on any other principle than that the right of the individual is always subservient to that of the mass. Any other creed spells rank individualism, and individualism carried to its logical conclusion means nothing more nor less than anarchy. In any system of ethics a right implies a duty. The physician's *right* to practice medicine by virtue of a license issued him by the state, protecting him in the exclusive privilege of healing the sick and shielding the well, implies a *duty* and an allegiance to the creator of that self-same right; and all other ethical ties to individuals or groups of individuals are insignificant when compared to the loyalty and protection demanded by the great social structure whose existence is always threatened, and whose efficiency is always impaired, by bacterial invasion. Every physician is a state officer, a public health officer, commissioned and protected by the state, and in this day and age not only is it his privilege to heal the sick, but it is his absolute duty to shield the well. He who practices today only the healing art, and leaves out of his medical armamentarium preventive medical science, is very poorly equipped. An individual has no rights that conflict with society's interests. In other words, an infected person's rights cease where community protection begins.

Again, we meet the argument that the reporting of venereal disease must inevitably result in blackmail, scandal and various other social calamities that are presumed to make the health officer shudder over the dire effects of his pernicious meddling in communicable diseases. Physicians have tried to be serious in explaining that the reason they did not report was the fear of being shot, prosecuted for libel, charged with malpractice, and what not. Their argument was always to bolster up something that they originally did not intend to do. As a matter of fact, Ohio has obtained the second largest number of venereal reports in the United States, and the cases there are reported by name and street number. Certainly, in most states where the reporting is done by some cipher code, all of these objections must perforce be groundless. But the point of the matter is, that even when the patients are reported by their names, no such catastrophes have taken place. At the risk of repetition and reiteration, may I again call your attention to the fact that the courts of the country have invariably upheld the venereal disease laws; and the responsibility is theirs, and not ours.

We are also admonished by the profession to have a care in enforcing venereal disease reporting in infected married men, lest their wives come into possession of the data, and domestic turmoil and tragedy result. Nowhere has the medical profession shown its lack of keeping up with modern economics and politics so much as by attempting to protect their own sex at the expense of helpless women and children. Why this maudlin sympathy for the venereally infected married man? You who have been struck with horror when your male syphilitic, in exceptional instances, acquired his disease from his wife: What about the hundreds of thousands of venereally diseased women who have conjugally acquired their maladies? What about the children who have innocently gone down in the struggle? Is it because you believe that men have a right to arrogate to themselves sexual privileges that they will not give, or is it because you are a man, and that despite the hand-writing on the wall you cannot overcome the prejudices of ages for men to repudiate the very sex that gave them birth. If these reports are to cause domestic discord; if the wife should through this system of reporting find that her husband is venereally diseased; if the fiancée of some venereally diseased man should by the remotest chance discover the true health status of her prospective husband—all of which I deny is at all probable under the reporting system in use—I ask you, not as physicians, not as scientists, not as sociologists, but as plain, reasonable men, were it not better that she have this information before she is infected than to have it thrust on her in the clinic, in the hospital, or on the other side of the river Jordan?

May I suggest to the profession to prospect just a bit. Would it not be well to anticipate woman's coming political power and, medically at least, give her the protection that each one of us expects legally for ourselves? Shall we, who are presumed to represent all that is humane and ideal in science, be pushed or shall we pull?

BENEFITS FROM REPORTING

If, then, there are no valid objections to the reporting of venereal disease, there ought to be positive benefits derived from reporting if the physician is asked for his cooperation. In the first place, statistical

data on venereal disease are urgently necessary. We ought to know our rate of infection. We should be thoroughly acquainted with the geographic distribution of venereal disease so that intensive work can be done in those heavily infected areas. We must have data of an accurate kind if we are to go before legislative bodies and civil communities to ask for funds. Some of the men engaged in this propaganda work have met with a peculiar situation; namely, they cannot get appropriations without statistical data, and they cannot get the data without funds to enforce the obvious duty of the physicians to report. Truly, a vicious circle.

Another important value in reporting is the recording of the patient so that he can be under surveillance in the event that he absconds from treatment. We have in this city returned for treatment in one clinic as many as twenty-seven patients in one day by threatening to placard their houses. We all know that much of the dissemination of the venereal diseases is due to inadequate treatment. With the abatement in their symptoms comes an indifference to ultimate cure, and it is only through a proper follow-up system that these patients can be compelled to remain in the physician's care until they are at least noninfectious.

Here in Louisiana we have on our report card a space for the reporting of the infector's name and address. Some physicians help greatly in acquiring this information. In most instances, I believe, it may be obtained from the patient if the physician will take the trouble to ascertain it. The patient's trauma is invariably mental as well as physical. If for no other reason than having his exalted ego wounded in misplaced confidence in his sexual selection, he will, by judicious questioning, reveal the source of his infection.

Where the state venereal disease laws are at all adequate, such an infector can readily be corralled. In the case of prostitutes, immediate action is imperative. The detention of a syphilitic prostitute militates against community syphilis to a degree few physicians realize. We have sent prostitutes to the State Detention Hospital from remote parts of the state on telegraphic order immediately on the receipt of a report card from a physician stating that this or that person had infected his patient.

CONCLUSION

Let us remember as physicians that we have no right, legal, moral or ethical, to violate a law. The venereal disease laws of the various states can accomplish results inestimable, but they are all based on the recording of the cases. This must be done by the practitioner. He will do it gladly, if he is true to himself and his community interests. He will do it by compulsion, if necessary. The time has passed when the state health officials should be expected to conduct educational campaigns among physicians. Neither the time, the money nor the patience is available to be wasted in persuasion when the offender is obviously negligent. The physician can be detected readily who evades reporting. He is not at all secure in the secret connivance with his patient. The laboratory diagnostician offers an excellent record of the practitioner's clientele of syphilitics; and the druggists' prescription files are an ideal place to dig out the protected patient with gonorrhea. But why should we be compelled to prosecute the very men who ought to give us aid?

ABSTRACT OF DISCUSSION

DR. OSCAR DOWLING, New Orleans: We have been unable to get the doctors of Louisiana to report their cases, even by numbers. They certainly ought not to be afraid of sending in a report with say "Number 16" as a case of gonorrhea, or "Number 76" as a case of syphilis, or "Number 87" as a case of chancroid. It is more important to have a case of gonorrhea or a case of syphilis reported than to have reported a case of smallpox or a case of leprosy or a case of diphtheria. A man suffering from a venereal disease is allowed to be at liberty. On the other hand, a woman who has the same disease can be confined in the isolation hospital in New Orleans. I do not recall more than one or two men who have been arrested and confined because they had a venereal disease. If it is necessary to confine the women, it is necessary to confine the men. I do not believe in two standards of morality, and I do not believe in two sets of laws for the treatment of these cases. I do not believe in a law which says that woman shall do one thing and a man shall not, or that a man can do one thing and a woman can not. If we can receive from you some suggestion or some plan whereby we can bring about the reporting of these cases, and whereby we can have them treated and cured, we shall be grateful.

DR. A. C. CHACE, Texarkana, Ark.: I wonder if you would be able to sleep when you leave New Orleans in your sleeper, if you knew that the train dispatcher, who is dispatching your train from one telegraph station to the next, had incipient paresis? And yet that happens. It was a feeling of duty toward the public which led the railroads with which I am connected to install what is termed a complete—although it is really incomplete—venereal service, and it is the only venereal service on any railroad in the world, so far as I know. After two years of practical experience with that service, certain points have been brought out that I think will answer, in a slight degree, what Dr. Dowling has asked about. Pennsylvania has seceded from the public health program on venereal disease. Dr. Martin has taken the stand that venereal diseases cannot be made reportable at present because the medical profession will not report them, and he does not believe in putting a rule on the statute books which cannot be enforced. If dangerously communicable diseases, diseases which are the most widely distributed among human beings of any communicable disease, are not reportable, then what diseases are reportable? On the other hand, the U. S. Public Health Service, which has done all that any one could ask for in the way of cooperation, is not using what is admitted to be one of the greatest weapons in this work, and that is the prophylactic or early treatment of venereal diseases. If we have a weapon which is effective in this work, why not use it? The answer, of course, is that churches and certain moralists are against it. I do not believe that is true, however. Dr. Martin has proved that it is not true, because he has put it through in Pennsylvania, and there has not been one single word of criticism from any one of nine million people. In regard to the question of not reporting venereal diseases, here is the only way—to prosecute the physician. It has come to that in every other state in regard to other communicable diseases, and it will have to come in regard to venereal diseases.

DR. W. D. CALVIN, Fort Wayne, Ind.: This paper emphasizes the need of a high central power, directly under the control of a national secretary of health. Then we will have efficiency. The attitude of Pennsylvania is directly attributable to this lack of central power. The fact that physicians in Louisiana are not reporting venereal cases is also due to the same lack of control. If it was a federal proposition, they would report their cases. It has been said by good authority that 8 per cent. of our population is syphilitic. The doctor who states that he has no venereal diseases, he has no syphilis in his practice, is blind, does not recognize that it exists. You cannot go anywhere and fail to see it. It is found everywhere. It is no respecter of persons. If it is true that 8 per cent. of the people of this country are syphilitic, then we have approximately one hundred syphilitics for every physician in the United States. Two propositions present themselves in regard to this question: The first is the general

practitioner's inability to diagnose syphilis, and the second is the lack of ability to treat it. Dr. Edler's statements in regard to the ambulatory clinic and free clinics is in itself a condemnation and censure of all men who do not know how to treat venereal diseases. The United States government, in the free clinics, is doing great work, and doing it better than it is done by the average physician. The educational proposition is most important. Every medical man ought to be willing to go out among the people with whom he lives and instruct them in regard to the dangers of venereal disease. It is by instruction given to the next generation that we will in large part assist in the eradication of these conditions.

We should at least report these cases to our state. There is some objection to making the reports locally, in certain places. You cannot quarantine cases of influenza because there is no law under which to report the cases. The same is true with regard to venereal disease.

DR. MILTON BOARD, Louisville, Ky.: A few days ago I was in the office of a specialist in our city who advised me that in the judgment of himself and his associates 60 per cent. of the cases of venereal disease were referred cases. If that be true, this is very largely a problem for the general practitioner, for the family doctor. If 60 per cent., or even half the cases which go to the specialists in the large cities are referred, then it follows naturally that practically all the cases in rural communities, and in smaller cities, are to be treated, and as a matter of fact are treated, by the general practitioner. The responsibility for the solution of this great civic problem rests on the shoulders of the American doctors. If we are to succeed we must have the conscientious support of the family doctor and not his antagonism. In Kentucky we have adopted two slogans. We print them in our literature, and we try to inculcate these principles in the minds of our people. First, we deny that venereal disease is a private affair between physician and patient. We claim that being infectious and communicable, it is a matter of public concern. Therefore, it should be handled as are other infectious and communicable diseases. Second, we deny that any individual with venereal disease has the right to infect any other person. We have put those principles into organic law of our state. Our state board of health is given wide power so long as it does not abuse this power. Our courts have done remarkably well in upholding our health officers in the wise and just enforcement of the law. Recently the legislature enacted a law creating a bureau of venereal diseases. We go further than that. We have the different towns and cities take action along these lines. The whole proposition resolves itself into the question of enforcement of the law. I agree with Dr. Calvin. The success of the federal law in this country is not the severity of the punishment, but the certainty of the punishment. If we are to get anywhere, the doctors must report these cases, and they must become missionaries in the cause. They must advise their patients of the danger they are to the community, and that if they do not keep within the law, if they do not refrain from spreading the disease, they will be put in quarantine. In our state full power is given for the quarantining of both males and females. Oklahoma sent a man to the penitentiary for five years for infecting a woman with syphilis. Every state should have that kind of a law.

DR. HARDIE R. HAYS, Jackson, Miss.: Ninety-four per cent. of the doctors of Mississippi presented morbidity reports on venereal diseases in 1919, but only a very small number gave us clinical reports. I wrote to the physicians of the state and asked them whether they were willing to give the doctors of the future some statistics by which they might see what was being done in solving the present-day problem of venereal diseases. I got quite a response to that circular letter, but some doctors did not even read the letter. In the next circular letter I told the physicians that if they did not read the literature which was being sent them under separate cover, the laity would soon be better informed on this progressive work than they were. This letter produced a great deal of interest, and a large percentage of the physicians of the state became interested in the campaign. As to the use of prophylaxis: In our "Keeping Fit" campaign we tried to

impress the boy that continence is rewarded with the highest physical and mental development. We cannot put prophylaxis on any basis which will be consistent with that plan of teaching. Women are going more actively into every phase of human endeavor. They work side by side with men; they are going to vote; they are going into every phase of life on the same footing as men and they have the same right to be immoral as men have. We must take the stand that there is only one standard of morals. We men must raise our standard of living so that the standard of womanhood will not have to degenerate to reach the single standard which is here to stay and must be adopted. If we advocate prophylaxis and encourage its use we will say to the world that we cannot raise the standard of morals in our people. I believe in teaching continence. It is the only teaching founded on the truth and that will finally lead man to the highest civilization. Doctors must demand a higher standard in their ranks and in their teaching.

DR. H. F. WHITE, Washington, D. C.: Our present campaign is divided into three phases which we considered essential in combating this disease: the medical, the educational and the legal. We feel that it is necessary to attack this problem from those three sides in order to control venereal disease. We believe from our investigations that many of those who spread this disease are mentally deficient. When such people are found they should be institutionalized. Those of a low grade of development should be kept permanently segregated; those of higher grade should remain until such time as they can take their place in society. That applies equally to both sexes. We have also learned that it will be necessary in the future to provide some logical, well-arranged plan of systematic sex education, beginning in the cradle, if necessary, and continuing at least through the premarital age. We must see to it that those who are suffering from this disease are given proper medical attention. Much has been said in reference to the value of prophylaxis and the need for it. The Public Health Service has investigated the subject very seriously, and during the war prophylaxis was tried out very extensively in the service. But from the studies we have made, and from what we are able to find out, we cannot endorse prophylaxis as being as valuable as the term would suggest. We found that the army, with the strongest military discipline, with punishment inflicted on any one who failed to live up to regulations, was only 50 per cent. efficient. Of course, there is also a moral question which we respect. We would rather have cooperation than dissension. But our principal reason for not talking about prophylaxis is because we do not believe it to be as efficient as it has been represented to be in the past.

DR. WILLIAM EDLER, New Orleans: A doctor told me that a prostitute had come to his office with a florid syphilis. The doctor told her she ought to have medication; that it would cost \$25 for a dose of arsphenamin. She said she did not have the money and left the office. Two days later she returned and laid twenty-five one dollar bills on his desk. Their source was evident. The doctor did not report that case to the city board of health, nor did he retain that woman in his office until the health officer could get her. That physician was a criminal, in my opinion, and should be prosecuted as such. If I were the head of that department of health and had the power I would revoke his license for a period of time. That is my whole interpretation of a venereal disease reporting campaign. It is not to beg doctors to report, but to go out and prosecute and show them that they must not violate the law.

How Much Are You Worth?—The average man contains the constituents found in 1,200 eggs, has iron enough to make four ten-penny nails, fat contents to make seventy-five candles and a good sized piece of soap, not to speak of a bowl of sugar. Considering that eggs are selling for 95 cents a dozen, matches at 6 cents a box, and candles for 5 cents each, \$582.84 is the actual worth of the constituents of a grown person, to say nothing of what the sugar he contains may be worth.—*Minnesota Public Health Association Journal*, Jan. 15, 1920.

DISEASES DUE TO INTESTINAL PARASITES IN COLOMBIA, AND THEIR TREATMENT

OTTO T. BROSIOUS, M.D.

Medical Director, Pato & Nechi Mining Company, Limited

PATO, COLOMBIA

AND

WILLIAM A. BISHOP, M.D.

WATERTOWN, MASS.

Since the publication of our preliminary report on chenopodium,¹ the opportunity has presented itself for one of us (O. T. B.) to study the human intestinal fauna of the interior of Colombia; so while in this article we propose to continue in large measure the

discussion of the use of chenopodium, it has seemed feasible to include remarks on the prevalence of parasites in this region as well as some of the experiences with them there.

The Pato and Nechi mines, gold dredging companies in the department of Antioquia, Colombia, are located along the Nechi River, a branch of the Cauca River, which is a branch of the Magdalena. They are situated about 7 degrees north of the equator, and about 450 feet above sea level. The weather is torrid and the humidity very high, even in the dry season (the temperature ranging approximately between 75 and 95 F.). The natives, chiefly negroes and mulattoes, are very poor; the majority go barefoot or wear thin sandals when traveling in the jungle. Their diet consists chiefly of rice, beans, "platanos" (plantains), meat and a great abundance of "panela" or brown sugar. Along the rivers, fish contribute largely to their diet.

The hospital of the Pato and Nechi mines includes: a large clinic for native and American employees, together with a considerable outside native practice. The three chief diseases with which it has to deal are malaria, syphilis and hookworm disease; of these, the last named is the greatest malefactor, especially when associated with its other allied intestinal conditions. Over 13 per cent. of the diagnoses made in the hospital during a period of twenty-six months were those of uncinariasis, ascariasis and amebiasis, and a large majority of this number came with symptoms pointing directly to these three diseases.

Of 600 routine stool examinations, covering a period of thirty months, thirty-seven were of white foreigners (mostly Americans), four were of West Indian negroes, and the remaining 559 were of native Colombians. Only thirty-eight of this number were found to be absolutely negative for all parasites, and twenty-six of these were white foreigners and black West Indians, while only twelve were natives. This gives a percentage of almost 98 as positive among the natives of this region for some one of the intestinal parasites. Of the 600 cases, the various parasites were noted as occurring singly or existing in the combinations reported in Table 1.

TABLE 2.—RELATIVE PROPORTION OF VARIOUS CLASSES OF PARASITES

Class of Parasite	Number	Percentage
Uncinaria.....	300	65
Ascaris.....	253	40 7/30
Trichocephalus dispar.....	204	34
Ameba.....	75	12 1/2
Strongyloides.....	61	10 1/2
Trichomonas, Cercomonas or Lamblia.....	22	3 1/2
Balantidium coli.....	2	1/2
Tapeworm (Tinea saginata).....	2	1/2
Oxyuris vermicularis.....	1	1/6
Bilharzia.....	1	1/6

The coexistence in symbiosis of the hookworm, roundworm and whipworm is strikingly characteristic of all the tropical lands of the western hemisphere.

Of the 600 stool examinations, the various classes of parasites appeared in the total numbers and percentages, as shown in Table 2.

For diagnosis, specimens were simply prepared on clean slides with a drop of water and cover-glass in the usual manner and examined with the low power; the high power being used for details; the specimens were first centrifuged, as recommended by Bass. The Bass method would surely have increased the percentage of positives; but it is almost unnecessary when the parasites are so abundant, although it must be essential for health officers; for example, those who give final examinations to the emigrants coming from the Orient, and who are treated on board ship en route to California, or to those guardians of public health who examine applicants for employment for the deep gold mines in California and China.² However, we do not pronounce a negative here until several specimens have been examined, covering usually several days.

When the diagnosis was established, the hemoglobin was taken and registered, after which the treatment was given and repeated (about every fifth day) until a cure had been effected. An interval of from one to three months, depending on the convenience of the patient, was then allowed to elapse before the hemo-

2. Compare articles by Dr. Herbert Gunn, San Francisco.

globin was again examined, in order to ascertain the improvement of the blood obtained from the treatment. The average hemoglobin percentage of 250 unselected cases harboring intestinal parasites, regardless of types or combinations, was found to be less than 47.

We think that we can safely state that this is the average percentage of the hemoglobin of the natives of the district of Zaragoza in which the mines are situated. One hundred of the above named unselected cases, taken at random, showed an average hemoglobin of 45.49 per cent. before taking treatment, and an average of 65.25 per cent. after taking a complete course of the therapy, making an average increase of almost 20 per cent. in the hemoglobin. Some of these cases showed marked improvement; for example, yielding an increase of 50 per cent. and over, in the hemoglobin; while others, as will be hereinafter submitted,

in persistent cases and in cases that presented only few hookworms, showed slight or no improvement.

The foregoing series contained all types. In another series, however, of fifty selected cases, the hemoglobin was raised from an average of 35.5 per cent. to 68.6 per cent., making an average increase of 33.1 per cent.

The hemoglobin, after treatment, improves very rapidly in young children and less rapidly in young adults; it responds more slowly after middle life. It is not uncommon to raise the hemoglobin in children 40 or 60 per cent. in two or three months after careful treatment. The normal percentage of hemoglobin is in all probability lower in the tropics than in the northern latitudes; and in attempting to raise the hemoglobin, it is here noteworthy that one commonly finds chronic malaria and syphilis present and other stubborn obstructions.

TABLE 3.—DIFFERENTIAL COUNTS

Case No.	Types	Poly-morpho-nu-clears, per Cent.	Large Mono-nu-clears, per Cent.	Small Mono-nu-clears, per Cent.	Eosino-phils, per Cent.	Trans-itionals, per Cent.	Mast Cells, per Cent.

* Filaria.

† Nucleated reds; poikilocytosis; anisocytosis; achromia.

‡ Nucleated reds.

There were cases, though fortunately these were rare, in which the hemoglobin actually continued to decrease even after thorough treatment. The red blood count and the hemoglobin gave a color index greater than 1; and although erythroblasts were found to be extremely rare, on differential counts, the polychromatophilia, anisocytosis, poikilocytosis, basic stippling and leukopenia presented a blood picture not unlike that of pernicious anemia. In three such cases, hookworm eggs were persistently found in the stools, though never in large numbers, after thorough and repeated treatments.

One patient died about four months after a course of treatment, showing no other pathologic manifestations; unfortunately, a necropsy was not permitted. The case presented a clinical picture of pernicious anemia. Another patient who came under our observation, and whose case was previously reported,¹ was given three thymol and two chenopodium treatments. His stools continued positive. At necropsy, the small intestine was literally filled with hookworms, which were embedded deeply in the mucosa of the valvulae conniventes of especially the duodenum and cecum.

As resident physicians in the hospitals of Aricon and Santo Tomás, in the Canal Zone and in Panama, respectively, where routine blood smear and stool examinations are made in all cases admitted, we had often heard discussions as to whether long-standing infections of intestinal parasites would or would not cause eosinophilia; and in this connection we were interested to learn from Dr. McClanahan's paper² that eosinophils were not increased in infestations of *Trichocephalus dispar*.

To investigate these questions, differential counts in 100 cases which appeared to be of long standing were made. The results are given in Table 3.

The result of the tabulation yielded ninety, or 90 per cent., as having shown eosinophilia; that is, a presence of more than 4 per cent. eosinophils. The average percentage of eosinophils in those showing the increase of these cells was 10.91. The high percentage of lymphocytes in some cases is due to the fact that there were quite a few children among the cases.

In eighty-three of the cases, hookworms existed alone or in combination with other parasites, and seventy-seven of these, or almost 93 per cent., showed eosinophilia. The average percentage of eosinophils in these cases was 10.86. Of the ten cases presenting *Ascaris* alone, eight, or 80 per cent., showed an increase in eosinophils averaging 8.5 per cent. to the individual. This series, as well as the three cases presenting *Trichocephalus dispar* alone and showing 14 per cent. eosinophils, was too small to submit any information of value.

UNUSUAL SYMPTOMATOLOGY

The general symptomatology of hookworm and roundworm disease is so well known that we will not repeat it, but we wish to mention some of the unusual symptoms and conditions that sometimes arise.

We have seen here diarrheas caused by hookworm alone. On several occasions, ascariasis and uncinariasis have caused severe abdominal pains, which were quieted by chenopodium treatment, with subsequent expulsion of the worms, when previously applied cathartics and other simple remedies had failed.

Ascarides existing alone have been known to cause severe anemia, which improved after chenopodium treatment; more often, however, the patient in this region first recognizes that he has roundworms when he vomits one or more during an attack of malaria or some other febrile complaint.

Ascarides causing suffocation when lodged in the trachea of children, and ascariasis necessitating surgical interference for various and remote reasons are also on record.

TREATMENT OF HOOKWORM AND ROUNDWORM DISEASE

In hookworm and roundworm disease we now use chenopodium exclusively. Salant⁴ has discussed the pharmacology of this drug. We do not wish here to discuss the superior merits, as a vermifuge, of the drug over thymol, for we are still strongly of the same opinion as when we presented our preliminary findings,¹ but we do want to bring out the fact that it has been possible to moderate the dose considerably, and we have found the diminished dosage equally as efficient as the larger doses and less troublesome to the patient.

UNTOWARD EFFECTS

At the Hospital Santo Tomás, and early in our experience with the drug, we were accustomed to give to adults two capsules of 8 minims each every two hours for three doses, followed in several hours by 2 ounces of castor oil. In that hospital, this therapeutic procedure was continued for eighteen months, during which time only one case was noted in which this drug was directly responsible for death. The patient was a cardionephritic, with a severe hookworm infection. At necropsy it was found that the kidneys had chronically degenerated.

Several cases of partial and one case of permanent deafness were noted, which were attributed to chenopodium by the majority of the staff. Those cases, however, which occurred in our wards, gave positive Wassermann reactions, the examinations of the ear revealing a nerve deafness, with normal drums. But it may be worthy of mention that the ill effects arose only with a second supply of the oil, none having occurred with the supply first received.

After the use of chenopodium at Pato was begun, it was taken up with some enthusiasm at Medellín, Antioquia, Colombia, but was quickly abandoned because of some unfortunate untoward results, namely, marked deafness in many cases and death in three, as reported by Dr. Gil in the *Revista clínica* of Medellín.

It is probable that some of the oils on the market have more toxic effects than others. Whether the varying toxicity is dependent on the purity of the product, its age, conditions of storage and manner of dispensing, or is due to idiosyncrasies of the individual are questions that need further study. But until such time as definite information is obtained, we feel that only the purest oils furnished by reliable drug firms should be administered.

In an attempt to lessen the possibilities of the untoward effects of the drug, the original dosage with which we worked at Santo Tomás has been modified. Soft gelatin capsules of 0.3 c.c. each were used, as supplied by reliable pharmaceutical houses. Undoubtedly the freshly filled hard gelatin capsules recom-

4. Salant, William: The Pharmacology of the Oil of Chenopodium, with Suggestions for the Prevention and Treatment of Poisoning, J. A. M. A. 69: 2016 (Dec. 15) 1917.

mended by Darling, Barker and Hacker⁵ would have yielded even a higher percentage of efficiency.

In the hospital of the Pato and Nechi mines, 430 cases have so far been treated with chenopodium, requiring 750 treatments, or an average of 1.75 treatments per case, without any marked or permanent deleterious effect. The worst symptoms that have been noted were nausea and vertigo, with slight temporary partial deafness such as follows quinin administration. These always passed away after the castor oil purge; but we acknowledge the slight, general depressing effect it often has, even when given in moderate doses. Vomiting has never occurred from this moderated dosage.

OIL AS A PROPHYLACTIC MEASURE

Following the suggestions of several writers on the subject, the taking of much oil or fats prior to and on the days of treatment has been recommended patients, and an apparent decrease in the toxic symptoms mentioned above has been noticed, possibly because the fat rendered the intestinal wall less permeable to absorption of the toxic principles of the drug.

Chenopodium should have infinite value in field work in hookworm therapy because of the simple method of administration, and because, as Weston stated in his discussion of McClanahan's paper³: "We seldom found a case of uncinariasis that was not complicated with other intestinal parasites, and the use of oil of chenopodium was equally effective in the elimination of these other intestinal parasites as with the uncinaria." Two treatments at least should be given with the safer dosage herein recommended.

Our experience has shown that dietetic restrictions and preliminary purges are unnecessary, which makes the treatment very simple for patient and nurse, and chloroform has seemed to us to be superfluous. A strong adult is given three capsules, two hours later two capsules, and after two hours, three capsules more. Three hours later, 2 ounces of castor oil are given. An adult woman receives generally only six capsules in the entire treatment, three doses of two capsules each, at two-hour intervals, followed by the castor oil. The doses for children are moderated almost in accordance with Young's rule, very young children being given the drops with a teaspoonful of sugar. It is safe to give a child 1 minim for every year of his age, to be repeated once in two hours, followed in three hours by the castor oil. In all cases, the condition of the patient is noted before the subsequent dose is given, and if there is evidence of much depression, the last dose is omitted.

As evidence concerning the efficiency of the moderated dosage, we tabulated the results produced in 100 unselected cases, showing the number of hookworms expelled, and the number of treatments necessary to produce a cure. Where ascarides coexisted, a record of their expulsion was also made.

It may be generally safe to call any case an absolute cure wherein the last treatment has expelled only ten or less hookworms, assuming that a subsequent treatment would yield nothing (we know, however, that this rule would not hold for some few very persistent cases, as hereinbefore cited). But with this as a standard, we may consider the first fifty cases as absolute cures; 120 treatments being necessary in these cases to establish fifty cures, making an average of 2.4

treatments to the absolute cure, with the decreased dosage. From this series of 100 cases, we learn that the first treatment almost always expels most of the worms. In 100 first treatments 30,548 worms were expelled, making an average of over 300 worms expelled in an average case of hookworm disease in the first treatment in this region. In the first fifty absolute cures, 19,867 worms were expelled, making an average of 397.34. In the same fifty cases, 16,593 worms were expelled by the first treatment, or 331.86 per case of the total worms. Thus, about 84 per cent. of all the worms were expelled in the first treatment, with this reduced dosage. In the first and second treatments together, in the same series, 18,994 worms were expelled, or 379.88 worms per case, making altogether 95.58 per cent. of the worms expelled in the first two treatments.

In view of the fact that hookworms cannot reproduce themselves in the intestine of the host, it is quite conceivable that great good is done even by giving only one treatment, wherewith most of the other associating parasites are simultaneously expelled, and the body's resistance is raised to battle with the persisting parasites. Of course, a thorough cure should always be effected when possible and convenient.

A record of 100 cases of infestation with *Ascaris lumbricoides* demonstrates that these respond to treatment more quickly and require fewer treatments for a complete cure.

In addition to uncinariasis and ascariasis, the chenopodium treatment has a slight effect on infestation with *Strongyloides*, but we believe this to be due more to the purge than to the anthelmintic. Saline purges alone will yield similar results. We have read with interest that chenopodium has established cures in amebic dysentery, but experimentation at Pato has not borne that out. However, we have seen the intestine cleaned with chenopodium from apparently harmless amebas (probably *Endameba coli*) existing without dysentery and ulceration of the intestine, and found only in a given series of routine stool examinations, probably because the amebas were free in the intestine and not deeply embedded in their characteristic undermined ulcers, as is *Endameba histolytica* in the disease which it produces.

When *Endameba histolytica* is concerned with the production of an active dysentery, we have found the emetin-bismuth combination so far to be the most satisfactory. We have not as yet given the emetin-bismuth-iodid preparation mentioned by Crowell⁶ a sufficiently long or thorough test to discuss it.

The muddy waters of the Nechi River, and the many little streams existing hereabout, laden with decomposing vegetable matter, reap their yearly death toll from the unfortunate inhabitants.

In 600 stool examinations, amebas appeared in seventy-five cases, making a total of 12.5 per cent. These were mostly *Endameba histolytica* and were producing active dysentery, which we are at present treating as follows: An absolute milk diet is prescribed. To a strong adult, a heaping teaspoonful of bismuth subnitrate is given four times a day for several days (depending on the severity of the case) and emetin hydrochlorid injections of $\frac{1}{3}$ grain, three times the first day, $\frac{2}{3}$ grain, three times the second day and 1

5. Darling, S. T.; Barber, M. A., and Hacker, H. P.: The Treatment of Hookworm Infection, J. A. M. A. 70: 499 (Feb. 23) 1918.

6. Crowell, B. C.: Treatment of Intestinal Amebiasis, with Special Reference to Ipecac and Its Derivatives, J. A. M. A. 69: 6 (July 7) 1917.

grain, three times the third day, making a total of 6 grains in three days, taken in progressively increased doses. After an interval of from three to four days, during which the bismuth alone is given, the emetin treatment is repeated as given before, and the bismuth is given only three times a day. After this, as the patient continues to improve, the bismuth is gradually decreased and the diet is gradually brought to the normal.

In very severe cases, opium and phenol are given with the bismuth, and intestinal irrigations, given high, of weak potassium permanganate solutions, have been found very effective.

After the bismuth-emetin treatment, we often administer tablets of bismuth subnitrate (5 grains), powdered opium ($\frac{1}{4}$ grain), aromatic powder (1 grain) and phenol ($\frac{1}{8}$ grain) with gratifying results. With this treatment we have had splendid success when given thoroughly, and have had few recurrences when there had been no hepatic complications. When *Endameba histolytica* has undergone cyst formation, the recurrences are less common, and these often successfully resist thorough treatments. We have not had sufficient time as yet to give a fair trial to the large doses of ipecac suggested by Dr. Simon⁷ of New Orleans in these persistent cases.

In this connection it will be of interest to narrate a unique experience of a refined and educated man who came under observation and examination, and whose veracity is unquestioned.

CASE 1.—As a mining engineer in Australia about twenty years ago, he became afflicted with an unusually severe type of amebic dysentery, so severe that he was told that he could not live. His wife nursed him, and several physicians attended him in consultation. His wife was instructed to inject rectally at regular given intervals a 20 c.c. syringe of a mixture of starch and laudanum, and to paint at the same time an ulcer of the buttock with tincture of iodine. In her newly acquired vocation as nurse, and in the attendant excitement, mingled with intense anxiety, she injected by mistake a syringe of the tincture of iodine into the rectum. From that time on, the man began to improve, and rapidly recovered. To this day he has never had a relapse. On three occasions, one of us (O. T. B.) has examined the stool, and no trace of amebas have been found.

It is noteworthy that chenopodium treatments for hookworm and roundworm disease have frequently, by their irritation of the intestinal mucosa, lighted up old amebic dysenteries, wherein the amebas were not detected on the first stool examination. Also we have seen cases here, wherein amebic dysenteries would not yield to emetin and bismuth alone, but these in conjunction with neo-arsphenamin proved effective, most probably because of a coexisting syphilitic ulceration of the intestine. Neo-arsphenamin alone is ineffective.

Chenopodium seems to have very little effect on whipworms, which, however, as far as we can ascertain, produce no ill effects, although they have been accused of many. Out of 600 stool examinations, 204, or 34 per cent., were positive for whipworms. Out of fifty cases, in which *Trichocephalus dispar* coexisted with uncinarias and ascarides, and in which chenopodium yielded a complete cure for the latter two types of parasites, *Trichocephalus dispar* eggs continued positive in the stool examinations in forty-six cases.

We rarely see whipworms in the examinations of whole stools after chenopodium treatments. Case 2 was an exception.

CASE 2.—A native woman, aged 20, was examined in this hospital for intestinal parasites after complaining of severe abdominal pains. The stool was found positive for uncinarias, ascarides and *Trichocephalus dispar*. Accordingly she was given a chenopodium treatment and passed 319 hookworms, twenty-three roundworms and thirty whipworms. Five days later a second chenopodium treatment was given which expelled eleven hookworms and five whipworms. The third and last chenopodium treatment a week later expelled only one whipworm.

The treatment of the flagellate protozoa with chenopodium seems equally as discouraging as the treatment of the whipworm. The diarrheas due to *Cercomonas*, *Trichomonas* and *Lamblia* yield well, however, to intestinal irrigations of methylene blue, or to weak solutions of potassium permanganate, given high, with opium, bismuth and phenol tablets given by mouth. These diseases have a peculiar faculty of subsiding in the temperate zones, untreated, but again recurring after long lapses of time—even years—on return into the tropics.

CASE 3.—A young English army officer recently came under the observation of one of us (O. T. B.). He acquired a severe *Trichomonas* infection, with diarrhea, in southern China several years ago, and was there treated, as far as could be ascertained, symptomatically. On his subsequent return to England, the diarrhea quickly disappeared. When the war broke out, he received his commission and was sent to Egypt on duty. Shortly after his arrival there, his old diarrhea again made itself manifest, and after some treatment he was transferred to the British Isles, where his diarrhea completely disappeared once more. After the signing of the armistice, he received his discharge and came to Colombia. Six weeks after his arrival, his old complaint again returned. At this time he became a patient at the Pato Hospital, received the treatment outlined above, and as yet has had no return of symptoms.

The diarrheas due to *Balantidium coli*, however, are most persistent. They resist all forms of treatment, including intravenous injections of neo-arsphenamin, which often is a valuable asset in the treatment of intestinal diseases in the tropics; probably because of the tremendous prevalence of syphilis.

Tapeworm is rare here because the natives cook all of their food well, especially the meats. In 600 stool examinations, only two were positive for tapeworm, and these were both *Taenia saginata*. One of these cases proved very interesting.

CASE 4.—A man, Colombian, aged 50, well developed and nourished, came to the hospital to be treated for tapeworm. He had been unsuccessfully treated elsewhere. The stool examination revealed uncinarias, ascarides and *Taenia saginata*. He was given a chenopodium treatment, with the intention of removing the hookworms and roundworms present, with the result that eighty-nine hookworms and two roundworms were passed. The attendant, trained to examine these whole stools, noted that many tapeworm segments were present in the stool, but not having been instructed "to look for the head," he neglected to do so. Four days later, the patient was given a thorough treatment for tapeworm, with aspidium, after which the whole stool examination, carefully rendered by several of us, yielded an absolutely negative result. Three days later another chenopodium treatment was given and only two hookworms were passed—absolutely nothing more. Four days later another aspidium treatment was given to confirm our findings, and as before, it expelled nothing. Evidently the chenopodium had removed the tape-

7. Simon, S. K.: Comparative Value of Ipecac and Its Alkaloids in Treatment of Intestinal Endamebiasis, J. A. M. A. 71: 2042 (Dec. 21) 1918.

worm, even without the preliminary purge which is so essential in the treatment with aspidium. Unfortunately, no similar cases have presented themselves since.

We have dwelt at length on the effects of chenopodium on the important intestinal parasites, with a view of submitting convincing evidence concerning the value of this drug in field work therapy of hookworm and roundworm disease. The decided improvement made in the thymol treatment by the addition of lactose and sodium bicarbonate is interesting, as is the recommendation by some writers of the use of chloroform for uncinariasis; but are these drugs as safe as chenopodium, when given in the dosage recommended herein, and are they as practical, when they are acknowledged to have an anthelmintic effect on only one class of intestinal parasites?

We have purposely omitted a discussion of the prophylaxis of hookworm and roundworm disease. These are so well known, as well as are the modes of infection on which they are based.

The control of amebiasis is more difficult because of the difficulty in educating the natives to the dangers of drinking the river water and water from many of the "quebreñas" or jungle streams, and to the necessity of drinking only water which has been boiled or filtered, or such as is supplied them by the companies.

SUMMARY

1. Hookworm disease is almost ubiquitous among the natives of the district of Zaragoza, 98 per cent. of the inhabitants being infected. We believe that with the centrifugal method of diagnosis this percentage might be made a little higher, and we also are of the opinion that this figure is almost generally applicable to all the inhabitants of the low hot lands of Colombia. Here, if anywhere, there is due need of hookworm campaigns, education and sanitation.

2. All forms of intestinal parasites apparently live and thrive in the same individual, no type producing conditions inimical to the life of the others.

3. We have come to the conclusion that the normal hemoglobin content of the natives of this region is somewhat lower than that of natives of the temperate zones; about 70 per cent., and think possibly this assertion may prove applicable to all natives of the equatorial belt. Our investigations have shown that the present hookworm infested population of Zaragoza has an average hemoglobin percentage of 47. Except in rare instances, a removal of the hookworms from the intestine of a sufferer is immediately followed by a rise in the hemoglobin percentage, without any other treatment being employed to bring this about. Doubt exists in our minds as to whether the exhibition of iron-containing medicines will accelerate or augment the normal gain that has been noted after a thorough removal of all hookworms. The gain in hemoglobin varies from 20 to 50 per cent., being most marked and most rapid in children, less rapid in young adults, and more slow after middle life.

4. Ninety-eight per cent. of a selected list of apparently chronic hookworm cases showed eosinophilia, and the average percentage of these cells in these cases was 10.91.

5. The unusual symptoms of hookworm disease, noticed in the cases coming under our observation, have been general depression, nausea and vomiting, and diarrhea. Severe abdominal pains are at times

traceable solely to the presence of hookworms or ascarides.

6. During our work with chenopodium at Santo Tomas Hospital, we saw several cases that exhibited toxic symptoms which we believed were attributable to chenopodium. Those symptoms were nausea, vomiting, general depression and weakness and vertigo, with deafness rarely permanent, usually being temporary. When permanent, it always had a background of syphilis or other preexisting disease. Deaths have been reported, one of which came under our observation.

Endeavoring to eliminate the possibility of these uncomfortable occurrences, the dosage of the drug was reduced from 48 minims to from 35 to 40 minims for a treatment, and we find that in 430 cases, 750 treatments were necessary to effect cures. Or, in other words, we have found that 1.75 treatments per case was necessary, in this series of 430 cases, to effect a cure. In a smaller unselected series, 2.4 treatments were necessary.

We feel certain that most investigators will agree with us that whatever the dosage, the great majority of cases will require more than one treatment thoroughly to remove the worms in a given case.

If the fact can be established that a 35 to 40 minim treatment is all that is necessary, and that in the great majority of instances two of such treatments will effect a cure, it should do much to lighten the field work of the hookworm commissions and operate to widen their scope and hasten results.

The fact that oil of chenopodium acts as a vermifuge to more than one of the other intestinal parasites is an added factor in its favor.

The result of these investigations shows that the first treatment always removes most of the worms; namely, about 84 per cent., and the percentage removal for ascarides is about the same (88).

7. *Ameba histolytica* occurred in 12.5 per cent. of the cases investigated, and we believe that this represents the average incidence of this disease in this district.

8. *Trichocephalus dispar* has an average incidence of about 34 per cent. In fifty cases treated with chenopodium, in which complete cures were obtained of the coexisting uncinaria and ascaris infection, only four were noted in which *Trichocephalus dispar* eggs could not be detected in the stools at the end of the treatment.

The Teaching of Internal Medicine.—In the efforts which have been made to improve the teaching of medicine, not infrequently that division of medicine having to do with the study of so-called internal diseases has received the least and last consideration. These diseases, however, because of the suffering and loss of life which result from them, are of far more practical importance than any other group of diseases. Of much more significance than this, at least from the educational standpoint, is the fact that the diseases of internal medicine are the ones which are most susceptible to scientific study, and thus far they are the principal diseases to which modern scientific methods of investigation have been applied. They are therefore the diseases with which the student of medicine should be chiefly concerned during his earlier years. It is in the study of these diseases that the student should develop his perspective and should obtain a knowledge of the methods which should be employed in the study of all other diseases.—Rufus Cole, *Science*, April, 2, 1920.

INFREQUENCY OF INTESTINAL
PARASITES IN YOUNG
CHILDREN *STAFFORD McLEAN, M.D.
NEW YORK

The object of this study was to determine the frequency of helminthiasis in children attending an outpatient department in New York City. There have been a number of studies made in recent years regarding the presence of intestinal parasites in children. Most of these investigations have been on children over 3 years of age, and the majority have been in institutions where the incidence of all diseases is higher than in children living at home. In the study made by De Buys and Dwyer¹ the stools were collected from seven institutions, and of the 595 individuals whose stools were examined, 53.2 per cent. were infected, the ages varying from 3 weeks to 18 years.

The outpatient department of The Babies' Hospital, where these stools were examined, is not a neighborhood clinic. The patients are recruited from all parts of the city. They represent a class sufficiently interested in their children's welfare to travel long distances for advice. This type of child is likely to live under better hygienic conditions and receive more intelligent care than the average child of the neighborhood clinic.

This study covered a period of five months, from July, 1919, to January, 1920. The stools were collected at random, without reference to the condition of the child or to the symptomatology. Many stools were examined of children who attended the clinic as visitors accompanying a sick brother or sister. Some were of children who attended for vaccination. Mothers attending the clinic with a sick child were urged to bring stools of their other children for examination. Some brought them because a neighbor believed the child had worms.

The routine procedure was to place the child on a vessel for a few minutes; if no stool was obtained, the child was given an enema of warm tap water; if this was unsuccessful, the parent was given a container and told to bring a fresh stool to the next class.

The method employed in this study for examination of stools was the brine flotation-loop method as perfected by Kofoed and Barber.² This method has the advantage of being simple and accurate. Kofoed and Barber found from 6 to 8 per cent. more hookworm infections by their method than by the centrifuge method. They found that the ova of the following parasites were floated up by the brine into the surface layer of the pool without distortion or noticeable change in appearance: *Ancylostoma duodenale*; *Ascaris lumbricoides*; *Trichuris trichiura*; *Taenia solium*; *Hymenolepis diminuta*; *Necator americanus*; *Oxyuris vermicularis*; *Taenia saginata*; *Hymenolepis nana*, and *Dipylidium caninum*.

Schloss,³ in 1910, made an admirable study of helminthiasis; his efforts were directed toward securing data regarding several phases of the subject. In con-

secutive examinations of the stools of 280 children he found that 28.57 per cent. harbored worms. The low percentage of infection reported here as compared with the high figures reported by Schloss may be due to the difference in the age of the children and to the fact that the children in this study came from better hygienic surroundings. In Schloss' study, 78 per cent. of the positive cases were in children over 5 years of age.

The samples of stools varied between 25 and 100 gm. in weight. The entire sample was thoroughly mixed with brine in a 350 c.c. tumbler. A disk of steel wool approximately one-fourth inch in thickness was used to force the particles of feces to the bottom of the tumbler. The mixture was allowed to stand approximately an hour, this interval allowing the ova time to ascend to the surface of the fluid. Several loopfuls of the surface fluid were then placed on a slide and searched with the low power. Frequently several slides of the same specimen were examined, about fifteen minutes being allowed to each slide. Except in a few instances, only one specimen was examined from each child. The examinations were made by two young women students of Hunter College. Their work was supervised by the hospital pathologist.

It was found that a history of symptoms commonly associated in the minds of the laity with the presence of intestinal parasites could be elicited frequently from parents of children over 12 months of age. The symptoms which the parents most commonly attribute to the presence of intestinal parasites are restlessness; at night, grinding of teeth, picking the nose and lips, loss of weight, capricious appetite and irritability.

Three hundred and eight stools were examined. Fifty-three stools from infants during the first year of life, sixty-six during the second year of life, sixty-four during the third year, fifty-six during the fourth year and sixty-nine from children from 4 to 12 years of age.

The number of stools found harboring intestinal parasites in the entire group of 308 cases was only seven, or 2.27 per cent. Of these seven cases, the presence of parasites was determined in four cases by the finding of ova, and in three by the presence of the parasites.

If the statements of the parents could be accepted regarding their findings of worms in the stools, the percentage would be higher. Fruit skins and strings of mucus may readily be mistaken by anxious mothers for some types of intestinal parasites.

Of the fifty-three examinations of infants during the first year, none were positive. Of the sixty-six during the second year, none were positive. Of the sixty-four during the third year, three were positive. In one child, 28 months of age, the ova of *Ascaris* were found; in another the same age, the *Ascaris* parasite, and in a third, 26 months of age, the *Oxyuris* parasite.

Of the fifty-six examinations in the fourth year, there were no positive cases.

Of the sixty-nine examinations in children from 4 to 12 years of age, four were positive; one, aged 6 years, with the ova of *Oxyuris*; another, aged 4 years, with the ova of *Ascaris lumbricoides*; another, aged 7 years, with *Oxyuris vermicularis* as well as the ova of *Ascaris lumbricoides*; and one, aged 4 years, with *Oxyuris vermicularis*.

* From the outpatient department of The Babies' Hospital.

2. Kofoed, C. A., and Barber, M. A.: Rapid Method for Detection of Ova of Intestinal Parasites in Human Stools, *J. A. M. A.* **71**: 1557 (Nov. 9) 1918.

3. Schloss, O. M.: Helminthiasis in Children, *Am. J. M. Sc.* **139**: 675 (May) 1910.

Of the sixty-nine children from 4 to 12 years of age, 5.7 per cent. harbored intestinal parasites.

Of the 189 children from 2 to 12 years of age, 3.7 per cent. harbored intestinal parasites.

It is possible that the ova of *Oxyuris vermicularis* might have escaped detection in certain stools, as frequently they are only found about the anal folds.

The examination of stools for ova in infants under 1 year of age is not customary. It was made in this study because many of the infants over 9 months of age receive the same variety of food in limited amounts as children during the second year of life, and in other ways are as susceptible to infection. The number of positive cases in the entire group is small as compared with the findings of other investigators. This low incidence of infection may be explained by the good hygienic conditions of the children included in this study.

SUMMARY

1. In an examination of 308 stools in children up to 12 years of age, 2.27 per cent. harbored parasites.

2. There were 3.7 per cent. positive in 189 examinations of children from 2 to 12 years of age.

3. In a group of sixty-nine children from 4 to 12 years of age, 5.7 per cent. were positive.

4. In another group of 189 children from 2 to 12 years of age, 3.7 per cent. harbored intestinal parasites.

CONCLUSION

Intestinal parasites are infrequent in New York City children living under good hygienic conditions.

17 East Seventy-First Street.

INCREASING THE PATHOLOGIST'S USEFULNESS AND HIS REWARDS

WITH DIRECTIONS FOR PREPARATION AND USE
OF A POLYCHROME METHYLENE BLUE
STAIN FOR FROZEN SECTIONS*

BENJAMIN T. TERRY, M.D.

NASHVILLE, TENN.

It is now extremely difficult for most universities to secure pathologists. This conclusion I have reached after talking with a number of pathologists, after having written to others, and after my own comparatively recent experience in attempting to secure an assistant.

It seems that few are entering and remaining in pathology. Present rewards are inadequate to attract men to become pathologists,¹ and the high cost of living is causing many of those who were in pathology to go into clinical medicine, where the rewards are greater.

The average pathologist is probably not properly trained to show his real value. He devotes more time to the pathology of the dead than to that of the living. He is usually taught that the diagnosis of frozen sections is unreliable. Nevertheless, rapid and reliable methods of diagnosis are necessary if the surgeon is to receive the assistance he needs during

an operation. If pathologists can learn to make reliable diagnoses from frozen sections, the value of these diagnoses to the clinicians will be very great.

Frozen section work is relied on where it is used extensively. Dr. William Mayo told me last summer that he did not see how the clinicians at the Mayo Clinic could get along without the aid which the department of surgical pathology is now continuously furnishing. Repeatedly surgeons at the Mayo Clinic stop in the midst of an operation to get a report from the surgical pathologist before deciding on the nature and extent of the operation.

EXAMPLES

A few examples² will show how diagnoses made from frozen sections may help the surgeon.

1. A patient has an ulcer of the lip which is excised for malignancy, but the microscopic examination shows that it is syphilitic. The surgeon's operative plan is halted by this diagnosis and the treatment is entirely altered.

2. A young woman has prolonged bleeding from the uterus. On account of her age the surgeon hesitates to perform a hysterectomy. He cures the uterus, however, and in the scrapings the pathologist finds carcinomatous tissue. The surgeon at once performs a hysterectomy.

3. The surgeon obtains a history of gastric trouble, and at operation the stomach appears to be cancerous. The neighboring lymph glands are enlarged. On examining these glands microscopically there are marked inflammatory changes present, but no evidence of malignancy is seen. If the area in the stomach after wide excision shows no evidence microscopically of malignancy, the prognosis and treatment will be determined by the pathologist's report.

Statistics from the Mayo Clinic based on 14,167 operative cases of all kinds show that a microscopic examination is necessary in 20 per cent. of the cases.²

If the statistics are limited to cases which are sufficiently difficult to necessitate the removal of tissue for diagnosis, the percentage of these cases in which the microscope must be resorted to may rise as high as 83.³

PROPER CONDITIONS

In order that the diagnoses on frozen sections may be reliable, four conditions should be realized:

1. The pathologist should be well trained in pathology, and in addition should be specially trained in the technic of cutting, staining and diagnosing frozen sections. In this work he should have had extensive experience.

2. There should be perfect cooperation between the clinician and the pathologist. The pathologist, in advance of his examination of the surgical specimen, should have full and free access to all the clinical data on the patient.

3. As often as possible the pathologist should be present at the operation and should receive the whole, unfixed specimen immediately after its removal from the patient. This specimen he should at once section in the gross in the laboratory nearby and, if a microscopic examination is necessary, he should select for this examination the part which his experience shows is most likely to be the best for his purposes.

* From the Department of Pathology, Vanderbilt University Medical Department.

* Read before the Section on Pathology and Physiology at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

2. MacCarty, W. C.: J. Lab. & Clin. Med. 4: 687 (Aug.) 1919.

3. MacCarty, W. C.: Minnesota Med. 1: 178 (May) 1918.

4. He should have an excellent stain for his work. Unna's polychrome methylene blue, after ripening, is a very satisfactory stain.

Unfortunately the method of ripening this stain has in the past required from six months to a year⁴ or more. The slowness with which the stain ripens has discouraged its use.

EXPERIMENTAL RIPENING

After seeing last summer through the kindness of Dr. MacCarty how rapidly and beautifully this stain works, I began in the fall a series of experiments to see whether a more rapid method of preparation could be worked out.

My first success was obtained by simultaneously aerating and stirring the solution mechanically at room temperature for ten hours a day for three weeks. By this means I secured 2.5 liters of excellent stain, and this stain is still good.

Later I found that I could dispense with both the mechanical stirring and the aeration, and could ripen the stain three times as quickly if I raised the temperature of the stain to 37.5 C. To make this stain I now place in a clean Petri dish 0.5 gm. of methylene blue (Bausch and Lomb), 0.5 gm. of potassium carbonate (Merck), and dissolve these in 50 c.c. of distilled water. The Petri dish is then left uncovered in an incubator regulated to 37.5 C. Each day the water lost by evaporation is made up by the addition of distilled water.

Under these conditions, each of the last twelve batches of stain has ripened satisfactorily in six days. The stain is tested on the sixth day on a frozen section of unfixed tissue. A piece of uterus is an excellent test object. The stain is regarded as satisfactory if all the nuclei are very sharply stained and if the smooth muscle in the uterus stains a sharp and beautiful purple when viewed by a good electric lamp provided with a daylight filter. If the stain is incubated at 37.5 C. for nine to fifteen days, it becomes rich in purple but stains weakly and unsatisfactorily.

TECHNIC

The technic of using this stain has been described in detail by Dr. Louis B. Wilson,⁴ from whose paper the following six steps are quoted.

1. Freeze bits of tissue, not more than 2 by 10 by 10 mm., in dextrin solution and cut sections 5 to 15 microns thick.
2. Remove the sections from the knife with the tip of the finger and allow them to thaw thereon.
3. Unroll the sections with a camel's hair brush or glass lifter in 1 per cent. sodium chlorid solution.
4. Stain 10 to 20 seconds in Unna's polychrome methylene blue.
5. Wash out momentarily in fresh 1 per cent. sodium chlorid solution.
6. Mount in Brun's glucose medium.

The fresher the tissues, the better the result. "Most failures are due to the fact that the cells are dead before the tissues are frozen."⁴ For many interesting details, Dr. Wilson's paper should be consulted.

ADVANTAGES OF THE METHOD

1. The method is extremely rapid. With the stains I have prepared, the staining is completed usually in from two to three seconds.

2. No preliminary fixation is necessary. This also makes for speed, as a tissue may be frozen as soon as it reaches the laboratory.

3. The unfixed tissue is seemingly more translucent than fixed tissue. This enables one to examine satisfactorily relatively thick specimens. Thicker specimens are more easily cut and handled than are thinner sections.

4 The nuclear stain is exceedingly sharp, and nucleoli are brought out with great distinctness by this method.

5. The stain has excellent differential qualities. This is not so evident in the nuclei as in the cytoplasm and in connective tissue fibrils. Epithelial cells have a somewhat bluish cytoplasm, while smooth muscle fibers are purplish, and the fibrils of connective tissue are faintly stained or take varying shades of red. The hyalinized intima of blood vessels usually takes an intense red, and the matrix of hyaline cartilage may also stain red. Bacteria are often well stained.

6. If properly carried out, the technic of staining frozen sections probably produces less shrinkage and fewer artefacts than are observed in tissues that are fixed and embedded in paraffin.

7. This stain is inexpensive to make and is easily prepared; moreover, it can be used over and over again, if after using it is filtered back into a bottle and the bottle is corked to prevent evaporation.

DISADVANTAGES OF THE METHOD

1. The specimens stained by the polychrome methylene blue method are not permanent. They may be kept a few hours, but in a comparatively short time the epithelial cells go to pieces. Up to the present no satisfactory method of preventing this has been discovered.

2. The method is of very little value in staining tissues that have been fixed in the usual ways. In fixed tissues the staining is not so sharp, and the color effects are less contrasting and less brilliant.

3. The method is also of less value in the diagnosis of tissues that have been out of the body for a long time before being received at the laboratory. Moreover, tissues which are necrotic stain less well by this method than they do after fixation and staining with hematoxylin and eosin.

4. The color effects with the polychrome stain are so different from those with hematoxylin and eosin that one has to become accustomed to the differences before one feels confident of the diagnosis.

SIMPLIFIED TECHNIC

A simpler technic than the one described by Dr. Wilson has given satisfactory results in our hands. Instead of freezing the tissues in dextrin, physiologic sodium chlorid solution or even tap water has been used without obvious disadvantage. Even the washing out of the stain and the mounting of the specimen may be done in Nashville tap water or in physiologic sodium chlorid solution. While not absolutely essential, Brun's glucose solution is, however, probably better for mounting the specimens than either water or sodium chlorid solution. I have not found it necessary to permit the sections to thaw out on the finger before placing in water.

RULES FOR JUDGING MALIGNANCY

In diagnosing malignancy in sections stained by the polychrome methylene blue method, the same

4. Wilson, L. B.: J. Lab. & Clin. Med. 1, October, 1915.

criteria are employed as in determining malignancy in sections that have been stained with eosin and hematoxylin. For details about morphology, invasion, metastases, recurrences, etc., the reader may consult any good textbook. Here I shall refer merely to a few points which I understand are especially stressed by Dr. MacCarty and Dr. Broders when examining fresh tissues stained by the methylene blue method.

MORPHOLOGY

1. Malignant cells depart from the normal in size and shape and often in the appearance of the nucleus. This departure of the malignant cells is in the direction of lack of differentiation. Undifferentiated cells usually have nuclei that are vesicular, round, oval or slightly irregular in shape, and they usually show a single, prominent nucleolus. These are the cells that Dr. Broders calls "one eyed cells." The presence in the specimen of many cells showing these variations in size and shape is suggestive of malignancy. If the variation is sufficiently great, Dr. MacCarty and Dr. Broders regard the cells as malignant. Malignant cells also depart from the normal in their relation to other cells and tissues, and in their greater rapidity of growth.

2. A large number of mitotic figures is suggestive of malignancy.

3. According to Dr. Broders, the presence of hyalinized fibrous tissue around atypical epithelial cells, especially in the breast, is suggestive "of malignancy or of a malignant tendency."⁵

INVASION

Malignant cells break barriers and invade the surrounding tissues. Occasionally benign tumors may invade; for example, angiomatous tumors.⁶ On the other hand, there are instances in which the basement membrane is not broken, and yet glandular cells are completely replaced by undifferentiated cells which correspond in practically every particular with cells which, if they had broken the basement membrane, would be regarded as malignant. MacCarty regards this stage as precancerous;⁷ but as the treatment is that appropriate for early carcinoma, it might be better to label it "early carcinomatous stage." Benign tumors are usually not invasive, and are frequently encapsulated.

Every pathologist who is doing tissue work should be interested in improving the service which he can render. His service should be greater if he masters the frozen section technic and finds that his diagnoses under proper conditions are as accurate with this method as with the more time consuming usual methods. Such pathologists should be in demand and they should be adequately rewarded. Universities will then probably be forced either to raise considerably the salaries of their pathologists, or else to require only part time service.

CONCLUSION

The salaries now paid pathologists by many universities are inadequate to cause many men to take up pathology as a profession. Other fields offer greater rewards. Frozen section work has been discouraged in the past as being unreliable. But those

who use the method most frequently are the most enthusiastic about it. A drawback to the diagnosing of tissues stained after being frozen and sectioned has been the lack of an easily procured, yet satisfactory staining fluid. A comparatively quick method of preparing a good stain is here described and directions are given for its use, as well as some rules for judging malignancy. It is hoped that many pathologists may be induced to try this method, for increasing the pathologist's usefulness is one of the surest ways of increasing his rewards. If pathologists become expert in diagnosing frozen sections they will increase greatly the value of their tissue diagnoses, and it should then be comparatively easy for them to earn salaries greater than universities usually pay.

ABSTRACT OF DISCUSSION

DR. WILLIAM C. MACCARTY, Rochester, Minn.: When I first went to Rochester I found Dr. Wilson's staining method in use and I have seen beautiful sections in paraffin and celloidin stained with this stain. I rarely see a celloidin or paraffin section now. We never make paraffin sections any more except when we want serial sections. We are getting a new idea of pathology from studying perfectly fresh unfixed cells. All our tissues are studied less than two minutes after their circulation is cut off, so they are practically alive when we get them. The sections are kept in isotonic solutions. There is just as much difference between studying tissues under these conditions and under the older conditions of fixation as there is between studying birds in the field and birds in the museum. The pathologist is a great aid to the surgeon and to the patient. You would be surprised to know how many patients demand that a certain pathologist examine their tumors. The layman is becoming educated to the necessity of the pathologist working with the surgeon. He is beginning to select his pathologist just as he selects his surgeon. Not a day passes that we do not render some great service to patients by Dr. Terry's method. I know of no other stain that we can use with the same efficiency. My experience with Dr. Terry's modification in preparing the stain has shown that it is an excellent method of ripening a stain.

DR. BENJAMIN T. TERRY, Nashville, Tenn.: If any one who is interested in trying the stain will send me his name and address, I will send him a sample so that he will not be put to the trouble of making the stain until after he has had an opportunity of testing it. I do not believe, however, that the preparation of the stain will be troublesome if the directions are followed carefully. With slower methods I have had trouble. Occasionally, under those conditions, the stain became infected and subsequently was found to have unsatisfactory staining qualities. With this six day method I have not had a single failure.

Symptoms of Breast Cancer.—The so-called classical symptoms of the textbooks are positively dangerous from the point of view of prognosis. To wait for their appearance is, in many cases, to wait till the disease is well-nigh incurable. The early signs of breast cancer are symptomless; the accidental discovery of a lump in the breast is usually the first sign of trouble. Pain is very rarely present at this stage, and here be it noted how extraordinarily difficult it is to convince many women of the very serious nature of a lesion which is causing no discomfort! The only other sign of breast cancer with which I am acquainted is dimpling of the skin of the breast over the tumor; this is never to be seen over nonmalignant tumors unless they have become infected. On the presence of a single hard lump in the breast of any woman over thirty years of age I am prepared to suspect cancer; if the skin dimples over the lump, I believe she has cancer, and that the least possible delay should take place in operating if our patient is to have a permanent cure.—W. Doolin, *Med. Press*, April 28, 1920.

TRAUMATIC ANEURYSM OF THE
RIGHT PULMONARY ARTERY *

HENRY C. MARBLE, M.D.

AND

PAUL D. WHITE, M.D.

BOSTON

History.—O. O., aged 25, a second lieutenant of infantry, who had served in the army four and one-half years, was admitted to Base Hospital No. 6, A. E. F., France, Sept. 5, 1918, with the diagnosis: perforating gunshot wound in the right chest; double pneumonia. The patient was wounded in action, August 5, with a perforating gunshot wound of the right chest. The field card, Evacuation Hospital No. 6, August 5, stated that a roentgenogram disclosed the right lung opaque with evidence of fluid; that there were signs of hemothorax; that the patient should be kept in the sitting posture, and that morphin should be administered. At Base Hospital No. 15, August 14, roentgenoscopy revealed pleural exudate in the lower right chest with intrapulmonary consolidation, and August 16, left peribronchial pneumonia. The patient entered U. S. Base Hospital No. 6 convalescing from double pneumonia. September 5 he was very thin and was constantly spitting up dark red sputum.

September 25, there was a pulmonary hemorrhage of 6 ounces of bright red blood. Repetition of the hemorrhage seemed to be uncontrollable. Transfusion was performed with temporary relief, but not complete hemostasis.

October 3, physical examination of the chest revealed dullness on the right side, bronchial breathing, and markedly increased whisper fremitus at the extreme right base posteriorly, especially close to the spine. No râles were heard. The heart was in the normal position; all sounds were normal, except for a murmur along the sternum, loudest at the lower end, continuous through systole and diastole and much accentuated with systole. There was no thrill anteriorly. The second sound at the aortic and pulmonary areas was normal, low in the right back at the angle of the scapula. The murmur was very loud, continuous in time with systolic accentuation, and heard loudest near the spine. The murmur sounded like the rhythmic increase and decrease of the roaring of dynamos, and was much louder in the back than in the front of the chest. Immediately after the examination the patient had a small pulmonary hemorrhage. The diagnosis made at that time was a probable arteriovenous aneurysm of vessels of the right lung with engorgement and hemorrhage over the right lower lobe.

November 30, the patient was becoming more anemic. A transfusion of about 500 c.c. was performed.

December 6, there was noted a good result from transfusion. The patient's color was much better. He continued to raise a little blood-stained sputum.

December 12, there was a hemorrhage of moderate severity.

Jan. 2, 1919, roentgenoscopy revealed a spherical area of shadow at the root of the right lung, from 8 to 10 cm. in diameter. January 3, at 3:45 a. m., the patient died suddenly of hemorrhage from the lungs.

Postmortem Examination (January 3).—There was a large aneurysm of the main trunk of the right pulmonary artery 4 cm. beyond the bifurcation of the pulmonary artery. The aneurysm was as large as a medium sized orange. The middle lobe and almost all of the lower lobe of the right lung were obliterated, but some lung tissue containing air in the periphery and especially at the extreme base remained. The valvelike hole from the aneurysm into the bronchus had thickened edges. Trabeculae of tougher tissue made up of obliterated bronchi crossed the aneurysm. The stomach was full of blood. The heart was normal.

COMMENT

This case of traumatic aneurysm of the right pulmonary artery is of interest because of its extreme rarity, the roentgen-ray findings and the type and position of the murmur heard in the back over the

aneurysm. Still another point of interest is the occurrence of the hemorrhages. The first one did not take place until more than a month after the wound; the pressure of the hemothorax may have prevented earlier bleeding from the lung. In all, there were between twenty-five and thirty hemorrhages, varying in amount up to 30 ounces. The hemorrhage was of the emetic type.

Operation was considered but not attempted. Thoracotomy posteriorly with collapse of the lung offered a hope of relief. At Paris, Chutro performed such an operation during the war with satisfactory result.

Traumatic aneurysm of the pulmonary artery or of the right or left main branches is extremely rare. Of course, damage to the pulmonary vessels, usually the smaller arteries or veins, is a common cause of death; but in the medical literature of the war we have found only one reference dealing specifically with traumatic aneurysm of one of the larger branches of the pulmonary artery. Even this was not, however, one of the main trunks. Konjetzny¹ in 1918 described one case—a soldier, aged 21, who suffered severe pulmonary hemorrhage two months after a chest wound and died of meningitis three months after his hemorrhage. Necropsy revealed an aneurysm of one of the branches of the left pulmonary artery.

Pulmonary aneurysms in general are also very rare. In 1906 Henschen² reviewed all the reported cases—forty-six in all, 53 per cent. male and 47 per cent. female—some of them thought to be due to syphilis or infectious disease. The correct diagnosis was made during life in only one or two of these cases. As a matter of fact, some of these cases were not saccular, but general dilatations of the pulmonary artery associated with a patent ductus arteriosus and so were essentially of congenital origin.

Since 1906, ten more cases of aneurysm of the pulmonary artery or of its main branches have been reported, one each by Genersich,³ Durno and Brown,⁴ Reiche,⁵ Ploeger,⁶ Entz,⁷ Zak,⁸ Nikolayeff,⁹ Warthin,¹⁰ Boinet,¹¹ and Konjetzny.¹ Of these cases, three showed also a patent ductus arteriosus. Nikolayeff⁹ gave figures of 271 cases of mediastinal aneurysms, among which were only two of aneurysm of the pulmonary artery. Warthin¹⁰ reported the first case of pulmonary aneurysm in which *Spirochaeta pallida* was found in the wall of the artery and in the aneurysmal sac.

At the Massachusetts General Hospital, among 3,500 necropsy cases in the twenty years from 1896 to 1915, there were forty cases of aortic aneurysm, six of cardiac aneurysm, two of aneurysm of the cerebral artery, and one each of aneurysm of the coronary artery, innominate artery, celiac axis, splenic artery, and femoral artery. There was no case of aneurysm of the pulmonary artery.

SUMMARY

In a case of traumatic aneurysm of the right pulmonary artery, the patient died of hemorrhage five months after the wound.

Fifty-six cases of aneurysm of the pulmonary artery or of its main branches have hitherto been reported, only one of which was of traumatic origin.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

POLLEN EXTRACTS-ARLCO.—Liquids obtained by extracting the proteins from the pollen of various species of plants.

Actions and Uses.—See general article, Pollen Extract Preparations, New and Nonofficial Remedies, 1920, p. 226.

Dosage.—See general article, Pollen Extract Preparations, New and Nonofficial Remedies, 1920, p. 226. Each of the Arlco products listed below is marketed in sets of four vials representing graduated concentrations, viz., 1:10,000, 1:5,000, 1:1,000 and 1:500, respectively; also in concentrated solution in capillary tubes for diagnostic tests, each tube containing sufficient for one skin test. For hospital use, the diagnostic solution is supplied in 1 Cc., 2 Cc. and 3 Cc. containers.

Aster Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the aster (*Aster multiflorus?*).

Birch Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the birch (*Betula populi-folia*).

Cherry Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the cherry (*Prunus species*).

Clover Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the clover (*Trifolium species*).

Corn Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the corn (*Zea mais*).

Dahlia Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the dahlia (*Dahlia variabilis*).

Daisy Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the daisy (*Crysanthemum leucanthemum*).

Dandelion Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the dandelion (*Taraxacum officinale*).

Dock Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the dock (*Rumex acetocella*).

Elm Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the elm (*Ulmus americana*).

Goldenglow Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the goldenglow (*Rudbeckia laciniata*).

Goldenrod Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the goldenrod (*Solidago species*).

Hickory Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the hickory (*Carya alba*).

June Grass Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the June grass (*Poa pratensis*).

Locust Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the locust (*Robinia pseudacacia*).

Maple Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the maple (*Acer rubrum*).

Narcissus Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the narcissus (*Narcissus species*).

Oak Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the oak (*Quercus species*).

Orchard Grass Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the orchard grass (*Dactylis glomerata*).

Poplar Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the poplar (*Populus balsamifera*).

Poppy Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the poppy (*Papaver somniferum*).

Ragweed Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the ragweed (*Ambrosia trifida*).

Ragweed Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the ragweed (*Ambrosia artemisiifolia*).

Red Top Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the red top (*Agrostis alba*).

Rose Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the rose (*Rosa rugosa*).

Rye Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the rye (*Secale cereale*).

Sunflower Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the sunflower (*Helianthus annuus*).

Timothy Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the timothy (*Phleum pratense*).

Walnut Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the walnut (*Juglans nigra*).

Willow Pollen Extract-Arlco.—A liquid prepared by extracting the proteins from the pollen of the willow (*Salix fragilis*).

Pollen Extracts-Arlco are prepared by the method of Walker (Am. Jour. Med. Science 157:409, 1919): To 0.5 gm. of the dry pollen are added 44 Cc. of sterile physiologic sodium chloride solution and the mixture is shaken thoroughly at frequent intervals for twenty-four hours. Sufficient absolute alcohol (6 Cc.) is then added to make the alcohol content 12 per cent. The mixture is thoroughly shaken at frequent intervals for twenty-four hours, after which it is centrifuged at high speed and the supernatant fluid is drawn off with a pipet. This liquid, therefore, consists of the pollen protein dissolved in a 12 per cent. alcoholic physiologic sodium chloride solution and it represents, by weight, 1 part of pollen in 100 parts of solvent. This 1 in 100 solution is used as stock and from it other dilutions, such as 1 in 500, 1 in 1,000, 1 in 5,000 and 1 in 10,000 are made. Cresol is added as a preservative.

ANTIPNEUMOCOCCUS SERUM (See New and Non-official Remedies, 1920, p. 269).

Lederle Antitoxin Laboratories, New York.

Antipneumococcus Serum (Polyvalent) (Lederle), Types I, II and III.—Prepared by immunizing horses (in cycles) with dead and living pneumococci of the three fixed types (Types I, II and III) and standardized against Type I culture according to Hygienic Laboratory method. It is of the same strength with regard to Type I as Type I serum and in addition contains antibodies against Type II and III; tricesol, 0.35 per cent., is added as preservative. Marketed in double ended vials containing 50 Cc. each, with sterile needle and tubing for intravenous injection; also in bottles containing 100 Cc.

PERTUSSIS BACILLUS VACCINE (See New and Non-official Remedies, 1920, p. 285).

Gilliland Laboratories, Inc., Ambler, Pa.

Pertussis Bacillus Vaccine-Gilliland.—Prepared from several strains of Pertussis Bacillus (Bordet-Gangou) grown on blood agar. The killed bacterial emulsion is suspended in physiologic solution of sodium chloride; three cresols, 0.25 per cent., is added as a preservative. Marketed in packages of four syringes containing 250, 500, 1,000 and 2,000 million killed bacteria, respectively; in packages of four ampules containing 50, 500, 1,000 and 2,000 million killed bacteria, respectively; also in 5, 10 and 20 Cc. vials containing 2,000 million killed bacteria per Cc.

THE PHYSIOLOGIC SIGNIFICANCE OF HUMAN MILK

When an infant is deprived of mother's milk, it is robbed of its birthright. There is no ideal substitute. The claims for the superiority of woman's milk in infant nutrition have been reechoed by almost every one who has devoted attention to the problem. But, in the attempts to explain the greater excellence of a secretion which in many respects resembles closely the composition of cow's milk, one may find marked diversity of opinions. The statement that the mammary glands have been evolved primarily to make a food that is best suited for rapidly developing human beings will not satisfy a scientific inquirer. Teleology should have a basis of fact as well as of good intention.

Some writers have ascribed the lesser excellence of cow's and other animal milks in comparison with mother's milk to a vague "foreign" character of the former. They are believed to be ill "adapted" to the human organism, producing objectionable reactions in the body, as "foreign" proteins are nowadays said to do. The proteins, in particular, entering into the artificial feeding of infants have been charged with being poorly digested. Cow's milk is far richer than human milk in proteins and casein in particular. The relative preponderance of lactalbumin in human milk is well known. Even admitting a possible difference between human casein and cow's milk casein, the majority of pediatricians will probably contend that the digestive apparatus of the healthy infant is equipped to digest properly the proteins from both species of animals. The occurrence of casein curds in the stools, about which so much has been written, is presumably a symptom of inadequacy of the individual rather than inherent unfitness of the food. Edelstein and Langstein¹ have summarized the matter by stating that normally there is no fundamental difference in the digestion of cow's milk proteins and human milk proteins by infants.

The assumption of indefinable or as yet undefined biologic or immunologic properties in human milk which peculiarly adapt it to the use of the species entails too much that is vague and intellectually intangible to be seriously considered. Digestion, which destroys the integrity of the food molecules and breaks them into comparatively simple fragments before absorption, must necessarily alter, if it does not entirely abolish, any larger structural basis which might be responsible for specific immunity or biologic advantage. Chemical investigation, however, has shown that lactalbumin, in which human milk abounds, is discoverably unlike its companion protein casein, which predominates in the cow's mammary secretion. The comparative yield of some of the indispensable amino-acids is quite unlike for these two types of proteins. Correspondingly, Osborne and Mendel,² in feeding experiments on small animals, have demonstrated that casein and lactalbumin have an unlike nutritive value, growth being more efficient on lactalbumin fed in equivalent amounts under otherwise unchanged dietary conditions.

This superior nutritive efficiency of lactalbumin has now been verified in an elaborate series of experiments by Edelstein and Langstein¹ in Charlottenburg. They determined for the first time the protein minimum and relative nutritive value of the nitrogen furnished as cow's milk, woman's milk, lactalbumin and casein, respectively, and established an advantage for lactalbumin and that type of milk—human milk—in which it abounds. The outcome is not a result of superior solubility or digestibility of different milk proteins. The advantage of the lactalbumin lies in its chemical make-up, as Osborne and Mendel have contended, whereby it supplies to better advantage than casein that relative proportion of amino-acid structural units needed in the growth of the infant. From this standpoint, Edelstein and Langstein remark, the peculiar proportions of albumin and casein in human milk deserve special consideration. We must shift our attitude from the contemplation of possible detrimental features of cow's milk proteins to superior merits of the human analogues. In this way we may perhaps sooner attain the ultimate end, foretold by Underhill,³ of assigning more or less specific functions to the various amino-acids, and indirectly indicating the relative efficiency of this or that protein in bringing about a desired result in nutrition.

Although human milk contains much less protein (though of perhaps superior nutritive quality, as indicated above) than does cow's milk, it furnishes considerably more lactose. Mathews⁴ does not hesitate to correlate the greater proportion of lactose in human

milk with the vastly greater brain development of human beings early in life. The myelinization of fibers in the brain requires galactose, yielded by lactose and seemingly formed only in the mammary gland. Let us bear in mind, however, that this view is mere hypothesis. A discussion of the lactose problem would soon bring us into troubled waters; but we believe that here, too, experimental science can find a way out into a place of clearer understanding.

INFLUENCE OF THE MALE IN THE PRODUCTION OF TWINS

The frequency of the appearance of twins in a family unquestionably has a hereditary aspect. It has been assumed, however, that inheritance from the paternal side can play little if any part in the tendency toward the birth of twins. As most of the latter represent plural births resulting from twin labors following double ovulation in the mother, it seems at first thought almost impossible that the father should exercise any influence in determining the twin production. There are, of course, cases of identical twins arising from a single egg by an early fission of the embryonic blastodisk, and these might be affected by paternal influence so far as the sperm cell as well as the egg cell might carry the tendency to twin-producing fission of the ovum. But the common view assumes that two-egg twins are due to simultaneous bursting of two graafian follicles, while single births result from rupture of a single ovum-discharging follicle. An effect of male hereditary tendencies in determining the number of such twins would therefore seem to be excluded.

Statistics collected by Davenport¹ of the Station for Experimental Evolution at Cold Spring Harbor, L. I., upset these seemingly logical assumptions. The data indicate that, from the hereditary standpoint, the father has about as much influence in the production of the twins as the mother. In explanation of this, Davenport points out that there is a good deal of evidence that single births are not always the consequence merely of the bursting of a single follicle. He emphasizes that there are several other factors that determine a single birth, such as the failure of one of two simultaneously expelled eggs to be fertilized, or the inability of one of two simultaneously expelled fertilized eggs to develop to maturity. If it should turn out that two eggs are ovulated more frequently than is at present recognized, the comparative rarity of twin births in woman might be due either to failure of fertilization or to failure of development of more than one egg.

On such possibilities the fathers may have an influence in relation to the production of twins. As Davenport interprets it, families that readily produce twins do so not only because in the mother the eggs were laid in pairs, but also because in the father the sperm is

active, abundant and without lethal factors, so that the number of eggs fertilized and brought to full term approaches a maximum.

Lethal factors probably play a more important part in relation to human germ cells than is commonly assumed. Failure of development is not an uncommon phenomenon in genetics. The number of corpora lutea in mammals that have large litters is usually greater than the number of embryos in the uterus. In gynecology, blighted twins are not unknown. It is stated¹ that in a fairly large proportion of all twin births, one of the twins has remained at a stage of development of the third, fourth, or even earlier month. The fetus is often compressed and flattened (papyraceous twin). The number of blighted twins that have been referred to in the literature amounts to several score, but naturally this is a very small proportion of the whole. As Davenport further recites, a record is made only of the larger blighted fetuses; the others are entirely overlooked, since search is rarely made for undeveloped embryos in the afterbirth, and the birth is consequently regarded as a single one. If he is correct in this, we may assume with him that a certain proportion, perhaps a large proportion, of fraternities that show two or three twin labors interspersed with single labors are those in which pairs of eggs have been ovulated in each case, but one of the pair has failed to develop, either through failure of fertilization or through early blighting.

PRIMARY POLYCYTHEMIA

Polycythemia—an increase in the number of red corpuscles or in the amount of hemoglobin per unit of blood volume—is not a rare clinical condition. True polycythemia should, of course, be carefully distinguished from relative increases in erythrocyte count due to concentration of the blood such as occurs after marked losses of fluid by copious diarrheas, profuse perspiration, or large localized edemas. In the latter conditions there is no absolute increase in the number of red cells, but merely a reduction in the amount of plasma in the circulation. A true polycythemia is likely to arise as the result of a comparative deficiency in oxygen in the respired atmosphere; hence its common occurrence at high altitudes, as has often been pointed out in *THE JOURNAL*. An increased number of red blood cells is frequently observed in the cyanosis of congenital heart disease. In all such instances the increment in pigment-carrying cells is evidently dependent on other pathologic or environmental changes, and therefore the designation of secondary or symptomatic polycythemia has been applied to the cases in question. In another group of persons, on the other hand, similar blood changes occur for which the cause is not so clearly established. They have been described as primary, essential or cryptogenic polycythemias. In exceptional cases, counts of red blood cells totaling 15 million per cubic millimeter

1. Davenport, C. B.: Influence of the Male in the Production of Human Twins, *Am. Naturalist* 54: 122 (March-April) 1920.

have been recorded, the hemoglobin being increased up to 26 gm. or over. This is true in so-called erythrocytosis megalosplenica, the malady brought into prominence by Vaquez in 1899 and Osler in 1903.

The pathogenesis of primary polycythemia (polycythemia rubra vera) is not yet known. It is evident that the number of corpuscles existing at any moment in the blood must represent a balance between factors of erythrocyte formation and destruction in the organism. Both processes are believed to be going on more or less continually in some degree in the body. Heretofore most attempts at an explanation of polycythemias have been concerned with the hematopoietic aspects. Thus, polycythemia has been attributed to a hyperplasia and hyperfunctioning of the bone marrow, and in fact vivid purple marrow has been described as an anatomic finding in certain characteristic cases. Another explanation, however, is likewise within the range of pathogenic possibilities. It is conceivable that the erythrocytes, formed without undue function in the bone marrow, are somehow protected from the ready destruction that is the usual fate of circulating red blood cells. This is the conclusion that Herrnhaiser¹ has adopted from the study of a new patient in von Jaksch's clinic at Prague. There was no occasion to assume the existence of a stimulation of the marrow, whereas an examination of the erythrocytes gave some reason to conclude that there was a decreased destructibility of the red cells. Hence in Herrnhaiser's case, at least, upset in the balance between production and destruction of cells was believed to be determined by an unusual conservation factor under conditions of normal hematopoiesis.

We must frankly admit ignorance as to the real determining factor in these polycythemias. Splenic tuberculosis has been abandoned as a probable cause of Vaquez-Osler's disease. Hyperplasia of the erythroblastic bone marrow has been accepted as a more probable pathogenic agency by some writers. Now we are asked to consider the possible rôle of decreased destruction of blood cells in producing a high absolute cell count. Perhaps each explanation may be applicable to certain cases so that true polycythemia is not attributable to a single causative process. For therapy it is not a matter of indifference as to which explanation is correct. If the marrow alone is involved, roentgen-ray treatment may give the best results. In several instances recorded it seems to have been helpful, as it is at times in improving conditions attending leukemia. But if the marrow is to be excluded from etiologic consideration, perhaps recourse to bleeding would offer a better prospect of relief. Hemorrhage has accordingly been tried with alleged advantage. Here, as so often, rational therapy awaits the determination of the exact cause or causes of symptoms that demand relief.

PHYSIOLOGIC EFFECTS OF EXERCISE IN THE TROPICS

Under ordinary environments, the human body engaged in physical exercise protects itself against undue changes of temperature by certain well known physiologic mechanisms. Muscular activity liberates heat in large amounts. The tendency to become overheated from this is averted by increased surface blood flow, increased perspiration, and, under favorable conditions, to a certain extent by the deepened breathing, which removes heat from the organism by warming the expired air and saturating it with aqueous vapor. Despite these protective devices, the adjustment to normal is not instantaneous or perfect. Exercise temporarily affects the pulse rate, blood pressure and body temperature in ways that have often been described. Indeed, the adequacy and promptness of the corrective responses to exercise are often taken as criteria of the efficiency of the circulatory apparatus of patients.

In the tropics, the added unusual environmental factors of a hot climate, often including great humidity, place a further task on the physiologic devices for counteracting the heat produced through exercise. How well and in what ways are these trying conditions met? There have been a number of investigations of the effects of heat and humidity on exercise, but they have for the most part been conducted under experimental conditions in temperate climates. Whether prolonged residence under the trying conditions of a humid tropical atmosphere would alter the physiologic performances is by no means clearly ascertained. A group of physiologists¹ working in the Australian Institute of Tropical Medicine at Townsville have made important records bearing on the subject. The climatic conditions during the hottest months of the year were essentially like those at Calcutta, the dry-bulb temperature standing between 80 and 90 F. with a highly saturated atmosphere. Vigorous exercise of short duration caused an increase in the pulse rate and blood pressure, both of which fell rapidly to the normal as in temperate climates, after discontinuation of the work. The corrective response to prolonged exercise was characterized by profuse sweating, so that very considerable losses of water often ensued. It was a quite common occurrence to lose as much as 1 kg. (2½ pounds) in weight during an hour's walk at a moderate pace; and even as much as 3.2 kg (7 pounds) might be lost in the course of a two hours' walk. The water eliminated under such conditions is derived almost entirely from tissues other than the blood, so that no pronounced concentration of the latter occurs. Otherwise, serious results might ensue.

Even in temperate zones, vigorous exercise may bring about a transient rise in body temperature. In Townsville, prolonged but mild exertion, such as walk-

1. Herrnhaiser, G.: Polycythaemia rubra vera, *Deutsch. Arch. f. klin. Med.* 130: 315 (Oct.) 1919; abstr. *J. A. M. A.* 74: 1549 (May 29) 1920.

1. Young, W. J.; Breinl, A.; Harris, J. J., and Osborne, W. A.: Effect of Exercise and Humid Heat on Pulse Rate, Blood Pressure, Body Temperature, and Blood Concentration, *Proc. Roy. Soc., London (B)*, 91: 111 (Jan. 1) 1920.

ing during the hot hours of the day, caused higher rectal temperatures, often amounting to 2 or 3 degrees Fahrenheit. The increase was more marked during the first part of the exercise than later. Hence, in contrasting conditions in the tropics with those obtaining elsewhere, the Australian observers remark that both exercise and humid heat play a part in producing a rise in blood pressure, pulse rate and rectal temperature. The degree of rise, however, is controlled by atmospheric conditions which influence the rate of cooling of the body.

Current Comment

HEREDITY AND ACQUIRED DEFECTS

According to the current theories of heredity there is a "physical continuity of the germinal material from generation to generation." Hereditary characteristics of the germ cells are not created anew in each generation; they are racial. To what extent, if any, what has been termed the morphology of inheritance can be altered or influenced in any one generation has been the subject of much discussion. Can acquired characters be inherited? In other words, can the environment seriously modify the fundamental features of the development of an individual so that new potencies or structural peculiarities will be permanently introduced into the race? There was a time, not long ago, when the possibility of altering the hereditary factors in the germ cells was accepted more readily than it has been in recent years. Mutilations of the body are not transmitted as new characters. Amputations of the tail in dogs or removal of the horns in cattle in successive generations have not brought about a tailless or hornless race. On the other hand, there are growing numbers of instances in which damage to the germ cells through an improper composition of the blood and tissue fluids which bathe them may lead to transmissible defects of the offspring. This has been shown experimentally as the outcome of intoxication with alcohol and by lead salts. A unique further illustration that the blood can convey modifying influences to the germ cells has been furnished by the investigations of Guyer¹ and his associates at the University of Wisconsin. They have reasoned that if the serum of one species of animal can be so sensitized to a given tissue or tissues of another species that it will become toxic or lytic for the tissue in question, it may be that there is sufficient constitutional identity between the mature substance of the tissue and at least some of its material antecedents in the germ that the latter may also be influenced specifically by the sensitized serum. This is, indeed, the case. When pregnant rabbits were injected with serum of an animal sensitized to rabbit-lens, antenatal lens defects appeared in the offspring. Opaque (and sometimes liquid) lenses and eyes otherwise defective were found. The effect of the lens-sensitized serum was specific; for the eye defects were

never observed in offspring of parents injected with serum sensitized to rabbit tissues other than lens. More significant, however, is the added fact that the defect once secured in the way mentioned may be transmitted to successive generations through breeding. In Guyer's experiments it has already been passed to a sixth generation. There is not merely a placental transmission of antibodies or other lens-damaging factors. The heredity of the acquired defects has been demonstrated by transmission through the male line, normal females being mated with defective eyed males. As Guyer and Smith remark, since the defect can thus be made to reappear in the descendants of a male with abnormal eyes when he is mated to a female from unrelated and untreated stock, it is obvious that it could have been conveyed only through the germ cells of the male, and that it may, therefore, be pronounced an example of true inheritance. We suspect that some of the current beliefs on the stability of good stock and the impossibility of damaging it through acquired blood changes will require revision in the near future.

ARTEFACT "SPIROCHETES"

The search for spirochetes in material taken for both experimental and diagnostic purposes from supposedly infected individuals is no longer an uncommon procedure confined to specialized laboratories. Dark field examinations for these significant micro-organisms are nowadays frequently made under a variety of conditions and circumstances. It is important, therefore, that all who are accustomed to work in this domain of microscopy should be made aware of the possible sources of error. For this reason, attention is directed to the recent warning by Eberson¹ of St. Louis regarding the appearance of artefacts—extremely tenuous, filamentous forms resembling *Spirochaeta pallida* in motility and spiral structure. Investigation disclosed that they are derived from the red corpuscles, may be produced at will, and bear no relationship whatever to the organism of syphilis. Apparently, earlier observations of them without a real appreciation of their accidental origin have given rise to the suspicion that these artefacts were possible stages in the complete development of *Spirochaeta*. Eberson's experiments seem to make it clear beyond question, however, that influences, such as H-ion content of solutions, tonicity and transfer from the usual environment, are sufficient for the demonstration of the phenomenon, and that the newly described bodies have nothing whatever to do with the life-cycle of the specific agent in syphilis.

1. Guyer, M. F., and Smith, E. A.: Transmission of Eye-Defects Induced in Rabbits by Means of Lens-Sensitized Fowl-Serum, Proc. Nat. Acad. Sc. 6: 134 (March) 1920.

Lowering Infant Mortality by Better Obstetric Teaching.—The teachers in midwifery at the medical schools should remember that if the suffering and mortality of childbirth is to be ameliorated, not only must the teaching of the medical student be improved, but also that of the midwife. The blame for the present large mortality and morbidity of childbirth cannot be laid solely at the door of the doctor or of the midwife; they are both involved, and no one who knows the facts could say that improvements in the teaching of both are not urgently called for.—*Lancet*, Dec. 13, 1919.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Chinese Doctor Convicted.—It is stated that T. Wah Hing, a Chinese herb doctor of Sacramento, was recently convicted of practicing in violation of the state medical act.

Fined for Practicing Without a License.—Rose Trattner of Los Angeles was fined \$300 and given a ninety days' suspended jail sentence for practicing medicine without a license.

Chiropractors Convicted.—It is reported that on May 12, Frances J. Freenor and Simon Mueller, chiropractors, were convicted at San Francisco for practicing medicine without licenses.

Osteopaths Exceed Rights.—According to report the health officer of Stockton has refused to honor a death certificate filed by J. C. Rule, an osteopath, showing that a 10 year old "infant" died after an operation for peritonitis and appendicitis. The health officer holds that an osteopath has no right to perform such an operation.—The certificate of Dr. William T. Harlan, an osteopath of Arbuckle, was revoked on the ground that he had used drugs and written prescriptions, which the certificate to practice osteopathy does not permit.

GEORGIA

New District Officers.—At the annual meeting of the Twelfth District Medical Society, held in Swainsboro, June 9, Dr. Edward B. Claxton, Dublin, was elected president, and Dr. Thomas E. Blackburn, Swainsboro, vice president. It was decided to hold the next meeting at Wrightsville, December 2.

License Revoked.—The Georgia State Board of Medical Examiners, June 10, revoked the license of Philip Dymont, now of Pasadena, Calif., on the grounds that Dymont did not graduate from the Homeopathic Medical College of Missouri in 1891 or in any other year and that he had a substitute take the examination for him. The evidence showed that Dymont was neither a graduate nor had he ever been a student at the college named. Evidence further showed that Dr. L. G. Wright of Chicago had written the examination before the Georgia board in 1914 by which Dymont's license had been granted. A year later Dymont obtained a license in California through reciprocity with the Georgia board. The fraudulent nature of the credentials was discovered through data on file with the Council on Medical Education of the American Medical Association.

ILLINOIS

Personal.—Dr. C. Cartledge of the University of Chicago has been appointed assistant professor of chemistry at Johns Hopkins University, Baltimore.—Dr. Downs, Bloomington, was assaulted in his office, May 22, by two men to whom he had refused to issue a prescription for liquor.

College Commencement.—At the commencement exercises of the College of Medicine of the University of Illinois, June 16, a class of forty was given the degree of Doctor of Medicine. Dr. David Kinley, president of the university, conferred the degrees and delivered an address on "Some Questions in Medical Education."

Work on Sanatorium to Begin at Once.—Reconstruction of Edward Sanatorium, Naperville, which was destroyed by fire in February, is to be started at once. Although the entire amount necessary for the rebuilding of the institution has not been obtained, a sufficient sum has been realized to permit the reconstruction work to be entered on at once.

Campus for Professional School's.—A site for the erection of the new schools of medicine, dentistry, commerce and law of Northwestern University, Chicago, was assured, June 15, when the board of trustees voted unanimously to buy the Fairbanks-Farwell tract at Chicago Avenue and Lake Shore Drive. The purchase price is more than \$1,900,000.

Physicians' Club Election.—At the annual meeting of the Physicians Club of Chicago, June 17, Drs. Frank Morton, Edward H. Ochsner, Truman W. Brophy, Joseph A. Capps,

Coleman G. Buford and Ralph W. Webster were elected directors. Prof. Frederick Starr discussed "Mexico of Today"; and at the meeting of the board of directors which followed, Dr. Truman W. Brophy was elected president and Dr. Victor D. Lespinasse was reelected secretary.

INDIANA

Hospital Projects.—The proposed new Methodist Episcopal Hospital at Gary is now under construction, the cornerstone having been laid recently.—At a special election, the project for the erection of a Vermilion County Hospital at Clinton, to cost \$100,000, was carried by a majority of 1,100.

Nurses Graduate at Indianapolis.—At its eleventh commencement the Methodist Episcopal Hospital Training School for Nurses graduated a class of fifty-one nurses, the largest class in the history of the institution.—Eleven nurses were graduated at the recent commencement of the training school of the Protestant Deaconess Hospital, Indianapolis.

MARYLAND

Personal.—Asst. Surg.-Gen. Henry R. Carter, U. S. Public Health Service, Baltimore, has sailed from New York for Peru, where he will take charge of the sanitary forces of the Peruvian government in their effort to stamp out yellow fever. During the past winter, Dr. Carter has been in charge of a Rockefeller Foundation party which combated the disease in the Piura district. His headquarters will now be at Piata, a seaport, where the fever is at its worst, and he will remain in Peru until next January.—Dr. Daniel H. Lawler, U. S. Public Health Service, Baltimore, is under treatment at the Union Memorial Hospital for serious injuries of the spine received when he fell 25 feet into a concrete culvert at Round Bay, June 12.

Immigration Station Turned Over to U. S. Public Health Service.—Immigration Commissioner-Gen. Anthony Caminetti recently visited the quarantine station at Fort McHenry, Baltimore, and it has been practically decided that the quarantine site and buildings will be turned over to the U. S. Public Health Service, for a year or longer, instead of being returned to the control of the local bureau of immigration. This solution of the problem was suggested by Commissioner Stump of the local bureau. With virtually no immigrants landing at Baltimore, the annual expenditure of from \$60,000 to \$75,000 would be unjustified. The site was given to the Immigration Service by the War Department in 1913, and shortly afterward Congress appropriated \$550,000 for the erection of buildings. The group was nearing completion when America entered the war and it was at once turned over to the War Department to form part of the U. S. Army General Hospital No. 2 group.

MICHIGAN

Nurses Graduate.—A class of four nurses was graduated at the recent commencement of the Mercy Hospital Training School for Nurses at Jackson.

State Health Law Upheld.—In the damage suit for \$10,000 brought by Nina McCall Rock against Dr. Thomas J. Carney, formerly health officer of Alma, Judge Moinet decided in favor of the defendant, June 4, and the court directed the jury to return a verdict of no cause of action.

Personal.—Major Harry C. Coburn, Jr., M. C., U. S. Army, late commanding officer Base Hospital Unit No. 17 at Harper Hospital, Detroit, was tendered a testimonial banquet recently at the Detroit Athletic Club by officers who were associated with him while on duty at Dijon, France.—Dr. H. B. Markham, Marquette, has been appointed acting assistant surgeon, U. S. Public Health Service, to fill the vacancy caused by the resignation of Dr. Frederick McD. Harkin.—Dr. Guy L. Kiefer, Detroit, has been appointed medical director of the Michigan State Telephone Company, succeeding Dr. Robert B. Hasner.

MINNESOTA

Hospital Items.—Dr. William J. Stock, Hastings, has purchased a building at Pierz and is having it remodeled into a hospital.—A building to house the nurses in the Southwestern Sanatorium, Worthington, is being built at a cost of \$74,000.

Southern Minnesota Physicians to Meet.—The midsummer session of the Southern Minnesota Medical Association will be held at Fairmont, June 28 and 29, under the presidency of Dr. Herbert Z. Giffin, Rochester. The banquet will be held the first evening.

NEW YORK

Personal.—Dr. William A. Groat, Syracuse, has been elected a member of the board of trustees of Syracuse University.—Dr. Alexis Carrel of the Rockefeller Institute, New York City, was awarded the degree of Doctor of Science by Princeton University, June 14.—Dr. Menas S. Gregory, New York City, has been appointed a member of the board of managers of the state reformatory for women, Bedford.

Sanatorium Superintendents Meet.—The annual meeting of the New York State Association of Managers and Superintendents of Local Tuberculosis sanatoriums was held in Syracuse, June 2 and 3. The session of the first day was at the chamber of commerce and that of the second day at the Onandaga Sanatorium. In addition to addresses by Dr. Hermann M. Biggs and Mr. Homar Folks, discussions were held on tuberculosis clinics, county tuberculosis nurses, the standardization of tuberculosis hospitals, necessity of laboratory work, and throat and dental work in tuberculosis hospitals. Resolutions were passed thanking Governor Smith for vetoing the Fearon bill, which would have divested boards of managers of county tuberculosis hospitals of the power to fix the salaries of hospital employees. The state department of health was invited to investigate the incorrigible tuberculosis patients problem with a view to designating a part of some state custodial institution for their care. Drs. John J. Lloyd, Stanley L. Wang and Edwin P. Kolb were appointed a committee to consider the plan of the American Sanatorium Association for standardizing tuberculosis hospitals of New York state. A legislative committee consisting of Drs. H. J. Brayton, John J. Lloyd and Edwin P. Kolb was appointed. Dr. Joseph H. Marshall, president of the board of managers of the Suffolk County Tuberculosis Hospital, was elected president of the association for the ensuing year, succeeding Dr. A. Clifford Mercer, Syracuse. Dr. H. St. John Williams, Dr. Aden C. Gates and Dr. Robert L. Bartlett were reelected secretary, vice president and treasurer, respectively.

New York City

Medical College Commencements.—During the past week Cornell Medical College conferred the degree of Doctor of Medicine on thirty-eight men and thirteen women. The John Metcalf prize for general efficiency in medicine was awarded to Alexander G. Davidson, who led the honor roll. The degree of Doctor of Medicine was conferred on fifty-eight men at Fordham University.

City Accepts Strauss Laboratory.—The board of estimate has accepted the offer of Nathan Strauss to turn over to the city his milk pasteurization laboratory for the benefit of the children of New York on condition that the city provide funds to carry on and extend the work. The board of estimate plans to appropriate \$31,691 to operate the laboratory for the remainder of this year.

Anthrax in Public School.—A student taking a vocational course in brush making at Public School No. 12 recently contracted anthrax. Dr. Frank J. Monaghan, acting health commissioner, has asked the board of education to adopt regulations protecting students from this danger. He has drawn a report of precautionary measures which will be presented to the commissioners of the department of education. The health department has for the present taken charge of all materials used for brushmaking in the public schools.

OHIO

Hospital Construction Postponed.—Owing to the high cost of materials and labor, the construction of the \$500,000 Masonic Home Hospital at Springfield has been indefinitely postponed.

Executive Secretary Appointed.—Mr. Guy M. Wells has been appointed executive secretary of the Academy of Medicine of Cleveland, effective June 7. The work of the executive secretary will include the organization of an information bureau for members of the organization, the increasing of membership among eligible physicians, the publication of a monthly bulletin and cooperation with the state medical association and academies of other cities in legislative and educational matters.

PENNSYLVANIA

Personal.—Dr. Edward Martin, state commissioner of health, has appointed the following officials to genito-urinary clinics: Dr. George S. Armitage, chief at Chester City; Dr. Walter Leonard Lynn, Kingston, Pa., assistant at Wilkes-Barre; Dr. Robert M. Hursh, assistant at Harrisburg, and Dr. Ray M. Alexander, Bolivar, assistant at Reading.

"Cancer Day."—Under the auspices of the committee on cancer of the Medical Society of the State of Pennsylvania, Tuesday, June 22, was set aside as "Cancer Day" for Scranton and vicinity. The object of "Cancer Day" is to increase interest in this disease with especial reference to more frequent early diagnosis and more prompt and efficient treatment. There were operative, demonstrative and diagnostic clinics, as follows: State Hospital, arranged by Dr. Edward A. McLaine, Scranton, and Drs. John S. Rodman, P. Brooke Bland, Edward E. Montgomery, all of Philadelphia; Hahne-mann Hospital, arranged by Dr. John L. Peck, Scranton, and Dr. George W. Roberts, New York City; Moses Taylor Hospital, arranged by Dr. Jonathan M. Wainwright, Scranton, and Drs. John G. Clark and John H. Gibbon, Philadelphia. An evening meeting was held in the Y. M. C. A. auditorium at which introductory remarks were made by Dr. Edward Martin, commissioner of health of Pennsylvania, chairman of the meeting; Drs. John G. Clark, Herbert L. Northrup, John S. Rodman, Edward E. Montgomery and Frank J. Osborne, executive secretary of the American Society for the Control of Cancer.

Philadelphia

Tablet in Honor of Dr. Mills.—A tablet in honor of Dr. Charles K. Mills was unveiled at the Philadelphia General Hospital, June 17. Dr. Mills resigned last October after forty-two years' service as chief of the neurologic staff at the hospital. The tablet is of bronze, 48 by 28 inches, with a bas-relief medallion of Dr. Mills' head surmounting it.

Experts Confer on Tuberculosis.—The Henry Phipps Institute, Seventh and Lombard streets, during the week of June 14, was the center of conferences attended by experts in tuberculosis from all parts of the country. Plans were discussed by the executive committee of the National Tuberculosis Association to further the scope of the modern health crusade, which aims to make the child's consideration of its health a part of the classroom program in schools.

University of Pennsylvania Surprises Retiring Provost.—The one hundred and sixty-fourth annual commencement exercises of the University of Pennsylvania were held in the Metropolitan Opera House, June 16. After conferring nine honorary degrees on prominent men, and awarding 863 degrees to members of the graduating class and delivering the annual commencement address, Edgar Fahs Smith himself was granted an honorary degree of Doctor of Medicine by the faculty of the school of medicine and the board of trustees. That action came as a complete surprise to the provost, the members of the graduating class and to many of the faculty. Dr. Smith had just completed conferring the honorary degrees, when Dr. William Pepper, dean of the medical school, announced that his colleagues of the faculty wished to confer the degree of Doctor of Medicine on Dr. Smith.

VIRGINIA

Hospital Sold.—The Hygeia Hospital, Richmond, owned and conducted by Dr. James Allison Hodges for nearly twenty years, has been sold to Dr. John R. Blair. The building is equipped as a general hospital with about forty rooms.

Smallpox.—During the first four months of the year, there were 1,821 cases of smallpox reported in the state with six deaths, as compared with 770 reported cases during the same period of 1919. In February, the disease reached its apex for the season, with 703 cases or nearly 600 more than for the corresponding month of 1919. Wise and Lee counties lead in the number of cases reported.

CANADA

Hospital News.—At present there are in Ontario 11,000 mentally deficient citizens and 8,000 nerve racked war veterans. There are only twenty-three institutions in that province where these patients can be cared for. Work at the new federal government institution near London, Ont., is being pushed rapidly to provide accommodation for them. Its capacity is expected to reach 8,000. It is being constructed on the lines of the Soldiers' Home at Dayton, Ohio.

Health News.—The Women's Labor Party, Hamilton, Ont., has requested that women be employed as inspectors under the department of health.—The federal government has apportioned the grant of \$200,000 for the campaign against venereal diseases approximately as follows: Ontario, \$57,000; Quebec, \$47,000; Manitoba, \$12,000; Nova Scotia, \$10,000; New Brunswick, \$7,000; Saskatchewan, \$15,000; Alberta, \$11,000; British Columbia, \$14,000, and Prince Edward Island,

\$1,900. The payments have been allotted on the basis of population.

Personal.—Dr. Delmar A. Craig, medical superintendent of the Byron Sanitarium, London, Ont., has been made medical consultant on the staff of the Massachusetts-Halifax Health Commission.—Miss Jessie L. Ross, for eight years engaged in public health work, president of the Public Health Nursing Association of Pennsylvania, has been appointed chief nurse of the Massachusetts-Halifax Health Commission, Halifax, N. S. She will reside in Health Center No. 1, being conducted in old Admiralty House, and in addition to directing the public health work from this center will give lectures on public health and tuberculosis nursing and coordinate the practical field service in the course for public health nurses, organized under the auspices of the Red Cross of Nova Scotia and Dalhousie University.

GENERAL

Association for the Study of Epilepsy.—The nineteenth annual meeting of the National Association for the Study of Epilepsy was held in Hosack Hall, New York Academy of Medicine, June 3, under the presidency of Dr. L. Pierce Clark, New York City. The following officers were elected: president, Dr. G. Kirby Collier, Sonyea, N. Y.; vice president, Dr. Joseph J. Williams, Woodstock, Ont., and secretary-treasurer, Dr. Arthur L. Shaw, Camden, N. Y. (reelected).

Bequests and Donations.—The following bequests and donations have recently been announced:

New Orleans Child Welfare Association a donation of \$5,000 by Mrs. Alfred Parker, New York City, in memory of her father, Mr. Leon Fellman.

Charity Hospital, New Orleans, \$37,806.82 for the restoration of the Miles Amphitheater, by the will of Miss Catherine Voss.

Charity Hospital, New Orleans, a bequest of \$5,000 for the hospital and \$1,000 for the ambulance fund, by the will of E. J. Bobet.

Dooley Hospital, Richmond, Va., a donation of \$11,000, by Major James H. Dooley.

The University of Washington, Seattle, \$100,000 to be used for research work in tuberculosis, by the will of Mrs. Frank McDermott, Seattle, Wash.

Grant Hospital, Chicago, \$5,000, by the will of Harry Rubens, Chicago.

Coordination of Child Health Activities.—The American Child Hygiene Association, American Red Cross, Child Health Organization of America, National Child Labor Committee and National Organization for Public Health Nursing have held several conferences with a view to the correlation of efforts, and as a result the council for coordination of child health activities has been organized which will act as an advisory agency with the following objects: to define and develop so clearly their own work that each organization will be working in harmony and cooperation with all the others; to develop new methods which will lead to meeting more effectively some of the special problems still unsolved; and to afford an opportunity for any organization dealing with the health of children to submit its plan or program for suggestions.

LATIN AMERICA

Plague in Mexico.—Two cases of bubonic plague were reported in Vera Cruz, June 18. A suspected case has also been found in Mexico City.

Chile Joins Red Cross League.—The central committee of the Chilean Red Cross Society with headquarters at Punta Arenas has joined the League of Red Cross Societies.

Aid Plague Sufferers.—The American Red Cross, Gulf Division, with headquarters at New Orleans, has volunteered its assistance to bubonic plague sufferers of Vera Cruz, Mexico, and has sent a supply of vaccines and rat traps on a special United States revenue cutter to United States Consul Foster at Vera Cruz.

Medical Societies Organized.—The León Medical Society has recently reorganized, with Dr. L. H. Debayle as president; Dr. F. Berrios, secretary, and Dr. Ecolástico Lara as treasurer. The *Gaceta médica de Nicaragua*, published at León, is the official organ of the society.—The physicians in Granada district of Nicaragua have also recently organized a medical society, with Dr. H. Pallais B. as the secretary.

FOREIGN

Sanitation in Palestine.—The American Zionist Unit, sent by the Zionist organization of America to make the Holy Land a safe place to live in, has taken up the question of malaria, and has practically driven the disease from the

country. Hospitals and clinics have been established in Jerusalem, Jaffa, Tiberias and Safed.

Physicians Marooned in Asia Minor.—Among the medical missionaries marooned in the interior of Asia by hostile tribes are Dr. J. S. Stewart, at Mardin; Dr. Urse Little, at Diarbekr, and Drs. W. H. Bell and Marion Wilson, at Marash.

Red Cross Hospitals in Flanders.—A hospital with a dispensary and accommodation for thirty inpatients is being constructed at Roulers.—At Houthen, an extensive skin clinic has been organized with accommodation for fifty inpatients.—The Werwicq Hospital possesses the only operating theater in the region.—Dispensaries have been equipped in the town hall or school in fifty-three villages in the region.—Four maternity wards have been established: one at Roulers, one at Werwicq, a twelve-patient ward at Peperinghe, and a fully equipped maternity hospital at Ypres.

Rumanian Medical Research Bureau.—The Institutul Medice Legal at Bucharest was established as a morgue by the Rumanian government in 1894, but has undergone constant and careful development since that time and now in point of efficiency is a revelation to men from foreign countries. The institute handles on an average 2,500 bodies a year. The bodies as a rule are claimed by relatives or friends before the expiration of the twelve days, when interment is made at public expense. Students from the medical school attend classes of the institute on two afternoons of each week, and two rooms in the basement contain a complete equipment for necropsy.

Personal.—Dr. H. Violle has been appointed by the League of Red Cross Societies as medical liaison officer between the central committee of the French Red Cross, the League of Red Cross Societies and the French Ministry of Health.—Dr. Massimo Selmo, Rome, has been appointed chief of the department of malaria of the general medical department of the League of Red Cross Societies.—Col. Richard P. Strong, chief medical director of the League of Red Cross Societies, has been unanimously elected to honorary membership in the Serbian Medical Society as an expression of the profound admiration of his scientific achievements, and as a mark of appreciation for the great sympathy which he showed to the Serbian people.—To continue his research on occupational hygiene, Professor Hellpach of the chair of psychology at Karlsruhe has been given an award of 6,000 marks. The exact field he is investigating is the "psychophysics of industrial work" and the "social psychology of organized labor."

Deaths in Other Countries

The cable brings word of the death of Dr. Gustav Zander, Stockholm, aged 85, whose name is known the world over for his system of medicomechanic exercises and apparatus. He began his efforts to correct and prevent curvature of the spine by this means in 1857, and in 1865 founded his private institute for the Zander exercises and apparatus.—Dr. J. de Freitas Pimentel of the Azores islands.

Government Services

Health Conditions in the Army

During the week ending June 11, only two new cases of pneumonia were reported, both from Camp Taylor. Sixteen new cases of malaria were reported, eight from the Southern Department. There were sixteen new cases of measles, of which six were from Camp Meade and four from Camp Dodge. There was one new case of scarlet fever from Camp Meade and one from Fort Logan. Of ten deaths from disease, four were due to tuberculosis and one to pneumonia, a death rate of 3.1 per thousand as compared with 4.0 in the preceding week. Excellent health conditions continue among the American forces in Germany, no deaths being reported during the week.

MEXICO CITY

(From Our Regular Correspondent)

June 2, 1920.

Plague Epidemic

The sanitary authorities of the port of Vera Cruz have reported recently the occurrence of several cases of suspected plague, and two in which the diagnosis was confirmed. The National Board of Public Health at once took the necessary measures; a well-equipped sanitary detachment was ordered immediately to Vera Cruz, having at its head Dr. O. González Fabela, who is an expert on this subject, having performed the same duty in 1902, when the plague imported from San Francisco invaded the city of Mazatlán. He was also the official delegate of Mexico at the International Plague Conference, held at Mukden several years ago. All land communication with Vera Cruz was immediately stopped, except for sanitary purposes, and all maritime traffic was placed in quarantine after the facts had been reported to foreign sanitary authorities, as required by international conventions. Immediate steps were taken to manufacture prophylactic vaccine, and a large quantity of antiplague serum was ordered from the United States. There were put in force without delay the accepted prophylactic measures, the effectiveness of which was recently demonstrated during the New Orleans outbreak (deratization, isolation, disinfection, etc.). So far, there have been eight cases reported, six of which were fatal. All these patients had the glandular type of the disease, no case having been observed so far of the pneumonic or septicemic type. The federal and local authorities will place at the disposal of the public health department all the funds required, and enforce strictly the necessary measures. As a gratifying sign of Pan-American solidarity, I must mention the fact that the American Consul at Vera Cruz offered, on behalf of the American government, the necessary assistance to combat the disease. His offer was accepted, as might be expected in view of the liberal policy of the new Mexican government.

Opium Smuggling

In a previous letter, mention was made of the fact that the National Board of Public Health had seized large quantities of opium, as traffic in it was considered unlawful, when not intended for medicinal purposes. It was reported afterward that the board intended to extract the alkaloids and use them in the hospitals. The owner of the opium did not agree to this, and taking advantage of the change of government requested that the drug should be returned to him. It was then found that the opium had been sold to some individual on condition that he should reexport it. The former owner has brought suit against Dr. Rodríguez, who claims in his defense that he followed the instructions of the government. The only thing certain about the matter is that this opium was shipped out of the country.

The Academy of Medicine

Among recent papers presented before the Scientific Research Association, mention may be made of one by Dr. F. Ocaranza, on Sixto's sign, in which there were copied several paragraphs from an article by the well known poet Rubén Darío entitled, "Don Juan's Inheritance," which shows that the poet was familiar with this sign of hereditary syphilis. Even more interesting was Dr. Perrín's address reporting the result of the investigation carried out last year in this city by Dr. S. B. Wolbach on the pathology and etiology of typhus fever. The Harvard pathologist thinks that the vascular and cutaneous lesions produced by this

disease are identical to those caused by the European typhus fever. He also alleges that in the vascular lesions of the Mexican typhus fever he has found an organism morphologically like the germ of Rocky Mountain spotted fever, but different in its grouping and distribution. Wolbach and his co-worker J. L. Todd have proposed for the new parasite the name of *Derma-centorxenus typhi*, on account of its analogy with the spotted fever germ, *Derma-centorxenus rickettsi*. They consider only barely probable that their organism may be identical to *Rickettsia prowazeki*. An article on this subject was published by them in the *Annales de l'Institut Pasteur* (34, No. 3, 1920). Drs. J. J. Izquierdo and Santiago Ramírez have been admitted as members of the academy, the first one in the section on physiology and the second in the section on medicine. Dr. Izquierdo, who is the incumbent of the chair of physiology in the school of medicine, presented a paper on the volume of glucose in the blood, based on sixty personal cases, and Dr. Ramírez, who is the editor of *El Observador Médico*, took for his subject, "The Syphilitic Plea."

Personal

The most recent political events have brought about several changes in the official medical personnel. Dr. Gabriel Malda has become the president of the superior board of public health, and Dr. Alfonso Pruneda the secretary. Dr. Rosendo Amor has become a senator, having been replaced as dean of the school of medicine by Dr. Guillermo Parra. The presidency of the national university, which was abandoned by Lic. Macías, May 7, has been assumed in succession by Lic. Antonio Caso, director of the postgraduate school, Lic. Balbino Dávalos, and finally by Lic. José Vasconcelos, a former secretary of education, and who until recently lived in the United States. Dr. Darío López has become governor of the state of Mexico, and Dr. Castillo Nájera placed in charge of the army sanitary service. The Real Academia de la Historia, de Madrid, has made a correspondent member Dr. Manuel Mestre Chigliazza, former governor of the state of Tabasco and a well known writer. Dr. Tomás G. Pellicer, who recently was Mexican consul at Philadelphia, has returned to this city and opened his office.

Amenorrhea and Marriage

Should a young girl who has never menstruated marry? This question, often propounded to the practicing physician, invariably proves embarrassing, as brought out recently in an interesting study by Dr. A. Siredey, physician to Paris hospitals.

Although in the majority of cases amenorrhea is caused by functional disorders resulting from general conditions which do not constitute a real obstacle to marriage, this is not true when the suppression of the periods is due to genital malformations absolutely incompatible with the conjugal state. Sometimes hermaphroditism, or more correctly, a sexual defect, is at fault, the greater number of such subjects being in reality members of the male sex. Even though the condition is somewhat rare, it should be considered. Less uncommon anomalies are the following: complete absence of the uterus with rudimentary vagina from 2 to 3 cm. long, or even without vagina. Siredey lays particular stress on the fact that the characteristics of girls with such anomalies may be exceedingly feminine. Therefore a detailed examination should be made, by determining the condition of the external genitals, by introducing a sound or uterometer into the vagina in order to determine its depth, by digital rectal exploration with the aid of a

sound in the bladder to make certain that no other organ is interposed between the bladder and the rectum.

One would be tempted to believe that such self-evident facts make the task of the physician easy; for when he has made known to the family the results of his examination the conclusions may be arrived at with sufficient clarity. However, far from meeting unhesitating acceptance, one is often obliged to combat the obstinate desire of the parents to marry off their daughter, even under such circumstances. In fact, it is absolutely necessary to prohibit the marriage of young girls who by reason of physical malformation are unfitted for conjugal life.

In well-formed young girls and women with normal organs, primary radical amenorrhea constitutes less of a real obstacle to marriage, since it does not exclude all hope of maternity, a factor which has been possible of determination. The amenorrhea following such acute diseases as typhoid fever, scarlatina and influenza is certainly compatible with marriage, as it yields to treatment in almost all cases. The amenorrhea of chronic diseases such as tuberculosis, malaria and cancer would not prove prohibitory if one considers only the physiologic side, for one sometimes sees under these unfortunate circumstances conceptions occur, almost invariably aggravating the condition of the mother who brings forth a stillbirth or a wretched being with little vitality, or one burdened with ineradicable defects. Such marriages are undesirable, and the physician should do everything to prevent or at least to postpone them until recovery has taken place. Transitory amenorrhea dependent on endocrine disorders, being serious only when it accompanies myxedema, Addison's disease and other diseases, does not constitute a contraindication except in these conditions. This can be discussed when rational treatment has led to a cure; there is always occasion to anticipate a relapse, and in reality, those with myxedema and Addison's disease have nothing to gain and very little to give in marriage. Young girls with so-called nervous amenorrhea showing thyroid instability, most often do not lose any of their aptitude for marriage. Encouragement of their designs and hopes sometimes suffices to improve their health and to cause disappearance of even the most inveterate troubles. Many of these girls may make splendid spouses and excellent mothers. In the case of those who have at the time dysmenorrhea and irregular menstruation with long periods of amenorrhea, if there are manifest signs of aplasia, it is preferable to do everything possible in order to put off the marriage. Their chances of maternity are very slight, their feeble constitution makes pregnancy very precarious. It should not be forgotten that very often these subjects are victims of congenital defects (syphilis, tuberculosis, etc.) which will be transmitted in a certain measure to their descendants.

Finally, Siredey calls the attention of physicians to the necessity of informing the relatives that in most cases of persistent or prolonged amenorrhea, marriage should not be decided on without apprising the fiancé or his family of the abnormal condition. The most elementary fairness demands this and it is the best means of diminishing the responsibility of the young lady and her parents. To avoid delicate explanations, the relatives are only too glad to entrust this duty to the physician. Siredey thinks that in order to maintain absolutely the principle of professional secrecy, the physician should refuse to make direct explanations to the fiancé or his family. It is sufficient to write to the parents of the young lady, summarily revealing the situation without going into details and giving the basic conclusions on the subject of marriage. The parents are free to communicate the letter to whomever they please. This method of procedure does not violate professional secrecy in the least and gives the desirable guarantees to the interested parties.

American Gift to the Société de Neurologie

At a recent meeting of the Société de Neurologie de Paris, the secretary-general read a letter from Dr. Hugh T. Patrick, Chicago, a foreign corresponding member of the society, in which the writer expressed his admiration for the work of French neurologists during the war and enclosed a check for 10,000 francs to help the society in continuing the publication of its transactions. The society unanimously voted its thanks to Dr. Patrick for his aid to the diffusion of its works, and expressed the hope that he, together with the new American members would attend the next annual Réunion neurologique at which collaboration could be established between neurologists of France and the United States. This reunion will be held July 9-10. Only one subject will be discussed: "The Clinical Forms and Treatment of Syphilis of the Nervous System." The titles of discussions and the names of those who anticipate being present should be communicated to the secretary-general, Dr. Henry Meige, 55 Rue de Grenelle, Paris.

Death of Pamard

Dr. Alfred Pamard of Avignon, a national associate of the Academy of Medicine since 1899, recently died at the age of 83. Dr. Pamard belonged to a long line of surgeons, perhaps unique in the history of France for it dates back to 1697, when Pierre Pamard established himself as physician and surgeon in Avignon and since which time the Pamard family has given Avignon many generations of surgeons and oculists.

LONDON

(From Our Regular Correspondent)

June 5, 1920.

Vital Statistics

The eighty-first annual report of the Registrar-General, for the year 1918, has just been issued. The estimated total civilian population of England and Wales is given as 13,777,100 civilian males and 19,697,600 females. The difference between the sexes is, of course, largely due to the number of men in the army during the war. The marriage rate was 15.3 per thousand, being 1.5 above the low rate in the preceding year (13.8) and 0.1 below the average in the last ten years, 1905-1914, which were unaffected by war conditions (15.4). The birth rate in 1918 was 17.7 per thousand, being the lowest on record. This rate was 0.1 per thousand below that recorded for 1917, and 6.1 below that for 1914, which, particularly, so far as the birth rate was concerned, might be regarded as the last year unaffected by war conditions. Even this large reduction, however, amounting in all to nearly 26 per cent. in 1918 as compared with 1914, is believed to compare very favorably with the experience of other belligerent countries. The provisional figures for 1919 indicate a recovery, showing an increase of 0.8 per thousand. The civilian death rate in 1918 was 17.6 per thousand, being 3.2 above the rate in the preceding year. The increased mortality was due to the epidemic of influenza. Apart from this, the year was one of extraordinary healthiness. The provisional figures for 1919 indicate a fall of about 3.8 per thousand, notwithstanding the continuance of the epidemic into the early part of the year. Infant mortality was 97 per thousand births, being 1 per thousand above the rate in the preceding year, but 10 per thousand below the average of the ten years 1908-1917. It is one of the four lowest rates hitherto recorded. As a result of the influenza epidemic, phthisis and pneumonia showed considerably increased mortality. On the other hand, decreased mortality was recorded for other forms of tuberculosis and diseases of the circulatory system. The remarkable increase in the deaths from tuberculosis in lunatic asylums, to which attention was drawn in

1917, continued in 1918. The deaths attributed to influenza in the year numbered 112,329, and throughout the epidemic 151,447, and the total mortality was estimated as close on 200,000. A table is given showing the annual average number of persons divorced during the last forty-two years. In the period 1876-1880, the total was 554; 1881-1885, 671; 1886-1890, 707; 1891-1895, 744; 1896-1900, 980; 1901-1905, 1,126; 1906-1910, 1,247; 1911, 1,160; 1912, 1,174; 1913, 1,154; 1914, 1,712; 1915, 1,360; 1916, 1,980; 1917, 1,406; 1918, 2,222. The increase in the latter years was no doubt largely due to the war.

The Crescograph

Sir J. C. Bose, the Indian scientist who has attained the distinction of F.R.S. for his experiments in plant life, has demonstrated at the Royal Society an instrument termed the crescograph which magnifies movements 2,000,000 times and demonstrates the growth of plants. Dr. A. D. Waller, F.R.S., the well known physiologist, who has for many years studied plant life, chiefly by electrical apparatus, holds that the effects shown by the crescograph are not vital but occur in dead tissues. At the Royal Society a discussion took place on the subject. By using an apparatus of his own which magnified only 1,000 times, Dr. Waller showed on a photographic plate the effect of electric stimulation on living plants, on plants killed by boiling, and on fiddle-strings. In the actual demonstration the so-called growth movements of Bose were shown with complete success on a fiddle-string, and with rather less success in the case of living and dead plants. In a somewhat animated discussion, the general feeling was that the crescograph was a valuable instrument, and, that, although Dr. Waller had shown by his own method the existence of responses to electrical stimulation in dead tissues closely similar to those which Sir J. C. Bose attributed to growth, he could not shake confidence in the Bose results unless he showed that the movements in fiddle-strings were also arrested by poisons and varied with other factors known to influence the rate of growth. Dr. Waller offered to leave his apparatus at the Royal Society, so that any fellows might themselves make experiments with it. He expressed the hope that Sir J. C. Bose would take a similar course. If that were done, it would be possible to make parallel experiments on the same materials with the two sets of apparatus, and so arrive at the only object of his criticism, the advancement of knowledge. Sir J. C. Bose, who had joined in the discussion, did not accept the suggestion.

Marriages

WILLIAM H. MONCRIEF, Col., M. C., U. S. Army, Washington, D. C., to Miss Ulah Lee Ensley of Covington, Ky., recently.

JAMES A. BETHEA, Major, M. C., U. S. Army, to Miss Margaret Hazel Bostrum of Philadelphia, June 2.

RUFUS EDWIN ADAMS, Comanche, Texas, to Mrs. L. Gwyn-dolyn Williamson of San Antonio, Texas, June 2.

CLYDE SUMNER CULP of Salineville, Ohio, to Miss Helen McLean Thompson of Toronto, Ohio, May 5.

VICTORIA CALLA A. BERGSTROM, Chicago, to Mr. James Francis Hill of New York City, March 8.

WILLIAM CHARLES BRONS, Queens, N. Y., to Miss Mary E. Stanton of Little Falls, N. Y., May 20.

ANDREW ROY MACAUSLAND, Boston, to Miss Katherine Brayton of Fall River, Mass., June 2.

THOMAS WRAY GRAYSON, Pittsburgh, to Miss Mary E. Bard of Meadville, Pa., June 9.

JULIUS FRISCHER, Kansas City, Mo., to Miss Marion Frances Sickles of Chicago, recently.

JOHN BAKER CARSON to Miss Francis Tyson, both of Philadelphia, May 26.

Deaths

John Warren Little ☉ Minneapolis; Jefferson Medical College, 1883; aged 60; president of the Minnesota State Medical Association in 1916; formerly professor of clinical surgery in the University of Minnesota; local surgeon to the Chicago and Great Western Railway; president and one of the founders of Hill Crest Hospital; surgeon to the Asbury and City hospitals; consulting surgeon to St. Mary's and Swedish hospitals; died, June 5.

Stephen Curtis Priest, Newark, Ohio; Eclectic Medical College of Pennsylvania, Philadelphia, 1869; Cincinnati College of Medicine and Surgery, 1877; aged 72; for thirty-three years medical examiner for the relief department of the Baltimore and Ohio system; once president of the Licking County Medical Society; for seven years major and surgeon, Ohio National Guard; died, May 31, from cerebral hemorrhage.

Edward Hervey Currier, Manchester, N. H.; Dartmouth Medical School, Hanover, N. H., 1881; aged 42; a member of the New Hampshire Medical Society and of the Association of Military Surgeons of the United States; chairman of the State Board of Medical Examiners for several years; physician to the Sacred Heart Hospital, Manchester; died, June 1.

Benjamin George Cool, Washington, D. C.; George Washington University, Washington, D. C., 1879; aged 65; a member of the Medical Society of the District of Columbia, and the Association of Military Surgeons of the United States; surgeon, Fourth Battalion, D. C. N. G., for twenty years; died at the home of his daughter in Washington, May 25.

Grover Cleveland Roberson, Hurricane, W. Va.; University of Louisville, Ky., 1909; aged 36; captain, M. C., U. S. Army, with service abroad, and discharged May 8, 1919; local surgeon for the Chesapeake and Ohio system; died, May 28, from injuries received by the overturning of his automobile while making a professional call.

William S. Harroun, Santa Fe, N. M.; Georgetown University, Washington, D. C., 1865; aged 83; physician to the United States Indian School of Santa Fe until 1917; assistant surgeon, U. S. Army, during the Civil War; at one time physician of Cook County, Ill.; died, about May 23.

Theodore Frelinghuysen Bliss, Springfield, Ohio; Geneva (N. Y.) Medical College, 1869; aged 77; formerly eye and ear surgeon to the Mitchell-Thomas Hospital, Springfield; died in Lansing, Mich., May 29, from cerebral hemorrhage.

Benjamin Addison Sawyer, Haverhill, Mass.; Harvard University Medical School, 1865; aged 77; assistant surgeon of the Fiftieth Massachusetts Volunteer Infantry during the Civil War; died, May 28, from heart disease.

Charles Jackson Pollard, Princeton, Ky.; Southwestern Homeopathic Medical College, Louisville, Ky., 1897; aged 46; a member of the Kentucky State Medical Association; died, May 26, from rheumatic endocarditis.

Frank Dean Patterson, Colorado Springs, Colo.; University of Michigan, Ann Arbor, 1893; aged 51; for several years physician in the United States Indian Service at Schurz, Nev.; died, April 10, from heart disease.

James Tipton Rice, Excelsior Springs, Mo.; University Medical College of Kansas City, Mo., 1889; aged 59; a member of the Missouri State Medical Association; died, April 6, from cerebral hemorrhage.

James Dewitt Clinton Hoyt, Elmwood, Ill.; Missouri Medical College, St. Louis, 1885; aged 77; a member of the Illinois State Medical Society; for many years a practitioner of Chicago; died, May 24.

Robert Lee Loftin, Olney, Ill.; Indiana University, Indianapolis and Bloomington, 1919; aged 32; an intern in the Olney (Ill.) Sanitarium; died in that institution, April 23, from meningitis.

Edward Horace Spooner, Park Ridge, N. J.; New York Homeopathic Medical College, New York City, 1869; aged 81; a veteran of the Civil War; also a clergyman; died, May 30.

George W. Garner, Stamps, Ark.; University of Tennessee, Nashville, 1880; aged 77; a practitioner for fifty years; surgeon in the Confederate service during the Civil War; died, May 29.

Charles O. Brock, Jefferson, Ga.; Atlanta (Ga.) Medical College, 1880; aged 62; a member of the Medical Association of Georgia; died, May 29, from chronic nephritis.

John Strobel • Philadelphia; Jefferson Medical College, 1880; aged 61; visiting physician to the Northern Day Nursery; died, May 28, from carcinoma of the liver.

Benjamin D'Arcy, Mayville, Mich.; Detroit Medical College, 1870; aged 80; a member of the Michigan State Medical Society; died, May 2, from cerebral embolism.

Thomas D. Hall, Oakland, Calif.; California Eclectic Medical College, Los Angeles, 1886; aged 71; a practitioner of Oakland for forty-five years; died, May 30.

Horace S. Hutchins, Batavia, N. Y.; Homeopathic Medical College of the State of New York, New York, 1861; aged 91; died, May 28, from bronchopneumonia.

Walter S. Hatfield, Walnut Hill, Cincinnati; Hahnemann Medical College of Philadelphia, 1882; aged 66; died, May 25, from carcinoma of the transverse colon.

Emma B. Standley, Alexis, Ill.; Northwestern University Woman's Medical School, 1887; aged 61; died in Kansas City, Mo., March 21, from myocarditis.

William Baxter Threlkeld, Providence, Ky.; University of Nashville, Tenn., 1905; aged 41; died at the home of his brother in Clay County, Ky., May 19.

Henry Barnabas Hill • Logansport, Ind.; Rush Medical College, 1895; aged 53; a specialist on diseases of the eye, ear, nose and throat; died, May 24.

William E. Bell, Osceola, Mo.; Missouri Medical College, St. Louis, 1880; aged 72; died in Kirkwood, Mo., May 20, from carcinoma of the intestine.

Herbert William Wilson, Toronto, Ont.; Trinity Medical College, 1889; aged 58; for many years a practitioner of Tamworth, Ont., died, April 24.

Jesse R. Harrod, Little Rock, Ark. (license, Eclectic State Medical Board of Arkansas, 1903); aged 57; died, May 23, from cerebral hemorrhage.

Gilliford Brown Sweeney, Pittsburgh; College of Physicians and Surgeons, Baltimore, 1886; aged 58; died, May 16, from cerebral hemorrhage.

Joseph Lander Sanborn, North Amherst, Mass.; Atlanta (Ga.) Medical College, 1894; aged 53; died, May 17, from cerebral hemorrhage.

William H. Herrick, Cleveland, Ohio; Western Reserve University, Cleveland, 1866; aged 75; a veteran of the Civil War; died, May 28.

Horace Greeley Boynton, Columbus, Ohio; Starling Medical College, Columbus, Ohio, 1888; aged 60; died, May 22, from heart disease.

Allan Gordon Rice, Toronto, University of Toronto, Ont., 1908; aged 35; division surgeon to the Grand Trunk System; died recently.

George Phineas Haley, Boise, Idaho; Jefferson Medical College, 1879; aged 66; died, May 29, from carcinoma of the stomach.

Orlando P. Shoemaker, Covina, Calif.; Northwestern Medical College, St. Joseph, Mo., 1885; aged 60; died, about May 24.

William Backus Cook, Chicago; Bennett Medical College, Chicago, 1882; aged 69; died, May 19, from cirrhosis of the liver.

Charles Carson Messer • Turner's Falls, Mass.; Dartmouth Medical School, Hanover, N. H., 1880; aged 66; died, May 20.

Elmer Legrand Straub • Minersville, Pa.; Jefferson Medical College, 1890; aged 54; died suddenly, May 31.

Henry James Allen • Corinth, N. Y.; University of Vermont, Burlington, 1884; aged 66; died, May 6.

Milton Grant Conger, Cincinnati; Miami Medical College, Cincinnati, 1890; aged 50; died, May 18.

Ulysses Montgomery, Louisville, Ky.; University of Louisville, Ky., 1873; aged 72; died, March 30.

Alfred Mullhaupt • St. Mary's, Pa.; Jefferson Medical College, 1884; aged 60; died, May 26.

Fred Augustus Hall, Roslindale, Mass.; Boston University, 1899; aged 52; died, about May 12.

John Edward Noble, Fannin, Miss.; Jefferson Medical College, 1870; aged 72; died, May 23.

Joseph Paradis Lavoie, Quebec; Laval University, Quebec, 1877; aged 65; died, April 15.

Correspondence

THE WORLD'S FOOD SUPPLY

To the Editor:—A recent issue of THE JOURNAL (June 12, 1920, p. 1650) contains a quotation from Mason to the effect that "today there seems reason to believe that in the whole world there is not all the food which could be consumed by all the people," and "for the first time in history the world at large faces a universal food shortage." Permit me to suggest that statistical foundation for these statements is not available. The United States Food Administration and the American Relief Administration records, supplemented by those of The International Agricultural Institute and the data of the Allied and Associated Powers, indicate that at the close of the present crop year the world may face a new year without a carry-over in bread grains. The future of bread will depend on the new planting and the following yield. Outside of wheat and rye, the world possesses supplies enough in hand and in prospect so that the population could be fed as in the past, if transportation and buying power were normal. Europe is eating less than normal; the rest of the world is eating more than normal, judged by prewar practice. If by a magic wand the transportation and exchanges of 1913 could be restored, the world would find the food in hand. The food supply would be less animal and more vegetarian, but it would be sufficient.

A. E. TAYLOR, M.D., Philadelphia.

Professor of Physiological Chemistry,
University of Pennsylvania.

"PRIORITY IN SUGGESTING TRANSILLUMINATION FOR FOREIGN BODIES"

To the Editor:—With regard to transillumination in locating foreign bodies, the question of priority in suggesting which was mentioned by Dr. Morris H. Kahn of New York (THE JOURNAL, May 29, 1920, p. 1536), I would remark that I used this method occasionally as early as 1900, both to detect foreign bodies and to note the shape of bones, though the rather surprising translucence of bones detracts considerably from the anticipated value of the method. The same remark applies to various foreign bodies. However, nothing is further from my intention than to claim personal priority for the method. The aborigines of Central America are reputed to have shaded areas with a mass of soft feathers where a foreign body was supposed to have lodged and to have inspected it against the sun's rays; and it is not unlikely that the method was used in some form by various peoples in prehistoric times. When our attention was first called to roentgen rays, I made a good many experiments with various methods of transillumination, by artificial light and sunlight, visually and by slow action on covered photographic plates, and doubtless many others did the same. In this connection, it may be of interest to note that my first attempts to locate the stomach with bismuth (and iron tablets which may be useful today for some purposes) were by roentgenography, but the experiments failed through lack of proper plates and unfamiliarity with the necessary technic. The first successful location of the stomach was by bismuth and the fluoroscope, early in July, 1897. Roux of Paris succeeded a few months before this time, but I was unaware of his work for several years afterward.

Transillumination should be more commonly practiced. Gastrodiaphany has properly fallen into disuse, as the results are vague and often misleading, and the roentgen rays or even auscultatory percussion give much more accurate infor-

mation. Transillumination as for hydrocele can often be applied to abdominal tumors and ascites, to give an idea of the consistency of the contents, some form of tube being employed to limit the field of vision. Too much dependence should not, however, be placed on the appearances. For foreign bodies, fractures, etc., especially in the hands and when the limbs are not too thick, transillumination with sunlight or a bright electric lamp, especially that of some form of projecting instrument, is often available when roentgenoscopic examination is not available. As stated, the bones are quite translucent and do not present the distinct shadows that might be expected. Still, a fracture or dislocation would be seen under favorable conditions. Foreign bodies, such as wood, which do not give a shadow with the roentgen rays, may be better seen by ordinary transillumination. Heavy cloth—for example, an old hat with a hole cut in it—may be used to obscure the light about the limb or part examined, and it may be necessary to reduce the illumination by gauze, by the aboriginal method of using feathers, or by some similar device, to secure a degree of transillumination at which the foreign body will show an opacity. Metallic substances will ordinarily give a distinct opacity, even including aluminum, and often the results are quite as decisive as with the roentgen rays. Wood, etc., may at times fail to give a recognizable shadow. It seems to me that the method should be taken up and carefully studied in its various details as a potentially valuable means of diagnosis and not merely as a rough-and-ready substitute for roentgen rays in an emergency.

A. L. BENEDICT, M.D., Buffalo.

TECHNIC OF SACHS-GEORGI REACTION

To the Editor:—Can you give me an outline of the technic of the Sachs-Georgi reaction?
J. C. L.

ANSWER.—The Sachs-Georgi reaction is a precipitation test for syphilis, based on the fact that the addition of cholesterinized organ extract to syphilitic serum will cause a flocculent precipitate.

A cholesterinized extract is prepared with alcoholic extract of beef heart, 100 c.c. (1 gm. of heart to 5 c.c. of alcohol); alcohol, 200 c.c., and 1 per cent. alcoholic solution of cholesterin, 13.5 c.c. At the moment of use, a quantity of the cholesterinized extract is gently agitated with an equal part of freshly prepared physiologic sodium chlorid solution (0.85 per cent.), after which four parts more of the sodium chlorid solution are rapidly added. It is very important that a 0.85 per cent. sodium chlorid solution be employed. Clear, fresh normal serum is obtained for control tests and is inactivated by heating at 55 C. for half an hour. The technic of the reaction is as follows:

To 1 c.c. of the patient's serum, diluted ten times with physiologic sodium chlorid solution, 0.5 c.c. of the dilute organ extract is added. These are mixed well and placed over a water bath at 37 C. for two hours, then kept at room temperature for from twenty to forty-eight hours, after which the results should be noted. The limit of forty-eight hours must not be exceeded as a false reaction may take place. Some serologists have obtained excellent results by centrifuging the tubes after incubation for three or four hours. A dissecting microscope makes an excellent substitute for the agglutinoscope in reading the results, for the inclined tubes may be placed on the black stage and examined for precipitates with the No. 8 lens. Parallel control reactions are run with the normal serum.

Iowa March Examination

Dr. Guilford H. Sumner, secretary, Iowa State Board of Medical Examiners, reports the written examination held at Iowa City, March 29-31, 1920. The examination covered 48 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 48 candidates examined, 47 passed and 1 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Northwestern University	(1918)	82.7
University of Illinois	(1920)	84.9
State University of Iowa College of Medicine (1917)		
92.1, (1920) 83.9, 84.7, 85, 85.4, 86.1, 86.5, 86.6, 86.9, 87, 87, 87.1, 87.1, 87.2, 87.4, 87.5, 87.5, 87.7, 87.9, 88, 88.1, 88.1, 88.4, 88.6, 88.7, 88.9, 89.1, 89.2, 89.5, 89.5, 89.6, 89.6, 90.1, 90.4, 90.9, 90.9, 90.9, 91.4, 91.7, 91.7, 92.

Rhode Island April Examination

Dr. Byron U. Richards, secretary of the Rhode Island State Board of Health, reports the written and practical examination held at Providence, April 1-2, 1920. The examination covered 7 subjects and included 70 questions. An average of 80 per cent. was required to pass. Of the 8 candidates examined, 6 passed and 2 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
George Washington University	(1917)	86.4
Johns Hopkins University	(1916)	85.2
Tufts College Medical School	(1917) 86.1, (1919)	82.1
University and Bellevue Hospital Medical College	(1919)	91.9
Montreal School of Medicine and Surgery	(1901)	90.4
FAILED			
Eastern University School of Medicine	(1913)	77.1
Tufts College Medical School	(1917)	74.2

Book Notices

LABORATORY MANUAL OF PHARMACOLOGY INCLUDING MATERIA MEDICA, PHARMACOPÆDICS AND PHARMACODYNAMICS. By A. D. Bush, B.Sc., M.D., Professor of Pharmacology, University of North Dakota. Cloth. Price, \$3.50 net. Pp. 251, with illustrations. Philadelphia: F. A. Davis Company, 1919.

This manual has been compiled with the object of better training medical students in the fundamentals of therapeutics and not for the development of specialists in pharmacology. Sections are included on pharmacology, materia medica, pharmacopædics and pharmacodynamics. The materia medica consists of testing the main properties of selected drugs from the pharmacopeia. The tests consist mainly of the appearance, odor, taste, solubility and the most important incompatibilities. Stress is laid on the unimportant differences between the obsolete word "pharmacopædics" and the word "pharmacy," though where greater accuracy of definition is attainable and more important, less care is used; for example, the statement is made that alcohol is obtained by the distillation of a fermented amylaceous substance, and two other alcohols are official: alcohol dehydratum and alcohol dilutum. The section labeled pharmacopædics is what is called pharmacy in most texts. It includes the preparation of a representative of each U. S. P. preparation and the examination of shelf samples of all official (U. S. P.) preparations. No "reasons" or "whys" are given for the steps taken in the processes. This section closes with the compounding of ten prescriptions written in Latin. No instruction in prescription writing is given. The section on pharmacodynamics consists of the usual class experiments, with an attempt to connect the laboratory work with work in the hospital. This is an excellent suggestion, altogether, too unavailable in most schools. The book closes with an outline of pharmacology based largely on Cushny's Pharmacology, and intended as an outline to guide the student in his studies. This part is well illustrated by diagrams. The student who satisfactorily works through the exercises given in this book should have an adequate knowledge of the foundations of therapeutics.

SWANZY'S HANDBOOK OF THE DISEASES OF THE EYE AND THEIR TREATMENT. Edited by Louis Werner, M.B., F.R.C.S.I., Surgeon to the Royal Victoria Eye and Ear Hospital. Twelfth edition. Cloth. Price, \$6 net. Pp. 671, with illustrations. Philadelphia: P. Blakiston's Son & Co., 1919.

To one familiar with the first edition of this book, published about thirty years ago, it is difficult to realize that the present edition is from the same author. Virtually every chapter has been rewritten and revised, and additions have been made that keep it abreast of the most recent advances in the science of ophthalmology. The value of colored plates in treatises on ophthalmology is becoming more and more recognized, and the editor has made a selection that will be of the greatest help to the student in acquainting himself with the various pathologic fundus conditions. With painstaking care, many things are explained in detail which might seem superfluous to the practitioner, but will be received with gratitude by the student. One of the noteworthy additions in the present edition is the chapter on ocular diseases and symptoms likely to accompany focal disease of the brain, in which a summary is given of Gordon Holmes' investigations on the cortical center of vision. The book will without doubt receive the highest commendation of the profession.

APHASIA AND ASSOCIATED SPEECH PROBLEMS. By Michael Osnato, M.D., Associate in Neurology, Columbia University. Cloth. Price, \$2.50 net. Pp. 190. New York: Paul B. Hoeber, 1920.

This small book gives a very readable account of aphasia and its associated problems. The author, in brief, abandons all the old ideas of cortical localization for speech. To him there is no such thing as sensory or motor aphasia—speech is the result of functioning of the entire brain. With this view most neurologists will not agree, for the many years of painstaking work on cortical localization cannot be thrown out, merely on theory; one must have some pathologic facts, which the author does not give. The book is well written, however, and the subject is adequately presented.

Medicolegal

Liability for Damages from Sale of Opiates

(*Moberg v. Scott* (S. D.), 175 N. W. R. 559)

The Supreme Court of South Dakota affirms a judgment in favor of the plaintiff, who recovered a verdict for \$12,500 damages in this action to recover actual and exemplary damages occasioned by her loss of conjugal consortium, as it was termed, during a period of illness preceding the death of her husband, and for damages resulting from his death, which sickness and death were alleged to have been caused by the defendant's unlawfully, wilfully, maliciously and knowingly furnishing the husband with commodities of which opium was an ingredient. The court says that it deems it unnecessary to review the evidence. It was largely circumstantial in its nature, but, while there was much conflict therein, there was ample from which the jury was warranted in finding that the plaintiff's husband, for the last year or more of his life, was in a physical and mental condition unfitting him to give to his wife that aid, support, society and companionship to which she was entitled, and which she had theretofore enjoyed; that such condition and the death which followed were caused by the husband's use of a drug containing opium; and that such drug was wrongfully, unlawfully and knowingly furnished the husband by the defendant. Lay witnesses could testify as to their observations touching the health, general demeanor, etc., of the husband during the time of his alleged illness and prior thereto. Nor was there error in allowing proof that the defendant had no license as required by local ordinance, authorizing him to sell opium or drugs containing opium. Such evidence was competent, both because it negated any right to sell even on a physician's prescription, and because it had a direct bearing on the good faith of the defendant, and therefore on the right of the plaintiff to recover exemplary damages. This court must presume that the jury found all the facts in favor of the plaintiff. If so, it must have found that the defendant had intentionally and wrongfully sold opium to the plaintiff's husband, knowing the character of the drug, and knowing that the husband was using it and being injuriously affected thereby. To so find was to find malice.

Cold and Fever Constitute a "Disease"

(*Sovereign Camp of the Woodmen of the World v. Treanor* (Texas), 217 S. W. R. 204)

The Court of Civil Appeals of Texas sets aside a judgment recovered by plaintiff Treanor and in its stead renders one for the defendant, in this action on an insurance certificate, because the case was apparently tried on a misapprehension of what was embraced within the term "disease." The court says that when the insured made his application for insurance he answered "No" to the question: "Have you ever consulted or been attended by a physician for any disease or injury during the past five years?" The medical examiner accepted that as correct, although he had himself not long before been called once to see the insured, who had what is designated in the case a "cold and fever." This was perhaps to be explained by the examiner's conception of the word "disease." But the word "disease" comprehends a cold and fever, as Webster defines the word "disease" as "a morbid condition of body; sickness," and gives the words "disorder" and "distemper" and "malady" as synonyms of the word "disease." The insured was sick enough to remain at home and to consult and to be attended by a physician. He was sick enough for his physician to prescribe medicine for him and to tell him to go to bed, and he had a cold and fever. It is clear to the court that his cold and fever was a disease comprehended by the plain and commonly understood meaning of the word "disease" contained in the question. The defendant had a right to ask all such questions, so that the medical examiner would be able to pass on the application to determine the risk or seek further information if

desirable. Neither the applicant nor the physician making the examination had the right to pass on what question to answer or the materiality thereof. Those questions were there for some purpose, and required a truthful answer. The word "disease" embraced the very ailments for which the physician treated the insured prior to his making the application.

(Concluded from page 1738)

The Disappearance of Foreign Bodies from the Circulation, and the Formation of Antibodies

DRS. WARFIELD T. LONGCOPE and GEORGE M. MACKENZIE, New York: The observations included in this report are based on a study of fourteen patients with pneumococcus Type I pneumonia who were treated with antipneumococcus serum, and received in this way from 100 to 630 c.c. of horse serum intravenously. The curves of precipitin and precipitinogen (horse serum) in the circulation, and the relation of these curves to the onset, duration and termination of the serum disease are shown. The presence of precipitinogen in the circulation and the time when it disappeared were determined by specific precipitation, using an antihorse rabbit serum. Repeated efforts to demonstrate the excretion of horse serum in the urine were, without exception, negative. The appearance of precipitins and the length of time during which they persisted in the circulation were followed by titrations of the patient's serum against normal horse serum. Several of the patients, however, were lost to observation before the precipitins had disappeared. Fresh serum was used in all tests, the tubes being set up in most cases the same day that the blood was drawn. In a few of the tests the serum stood in the ice-box overnight before being used. After being set up, the tubes were placed in the water bath for one hour, when the final reading was made. The titrations in each case were made by using dilutions of the antigen and a constant amount of precipitating serum.

With one exception the fourteen patients fall into two distinct groups. In the first group there were eight patients. These were all characterized by (1) severe serum disease; (2) a high titer of precipitins in the circulation, which either first appeared or rose to the crest of the curve synchronous with the termination of the symptoms of serum disease; and (3) disappearance of the precipitinogen near the time that the symptoms were subsiding. The onset of the serum disease in this group varied from the third to the eleventh day after the first administration of serum; the duration varied from eleven to twenty-eight days. The horse serum disappeared during the period between the eighteenth and the thirty-eighth day. Precipitins made their first appearance between the sixth and the fifteenth day, and in four of the eight patients were still present when the patient was lost to observation—from thirty-eight to fifty-seven days after the first dose of serum. In the other four the precipitin reaction was first negative on the twenty-sixth, fifty-seventh, sixty-sixth and forty-first days, respectively. In the second group there were five patients. They were characterized by (1) very mild or complete absence of symptoms of serum disease; (2) inefficient precipitin formation or none at all, demonstrable in the serum, and (3) a persistent reaction for horse serum in the circulation. In four of the five patients the

reaction for horse serum was still positive when the patients were lost to observation, the last test having been made on the forty-ninth, sixty-seventh, fifty-second and sixty-third days, respectively. In the other patient it was negative on the sixty-ninth day.

One patient out of the fourteen showed a marked serum disease of fourteen days' duration, precipitins of high titer and persistence of precipitinogen for seventy-six days. This patient was studied before we began testing the antihorse rabbit serum for traces of antigen, and it is possible that the apparent persistence of precipitinogen in the patient's serum was due to antigen in the rabbit serum, precipitated by the precipitins in the patient's serum.

The full significance of these interesting relations between serum disease, precipitin formation and disappearance or persistence of precipitinogen, which the results indicate, is not yet clear. But obviously, they suggest that those individuals who have mild serum disease or none at all, following administration of heterologous serum, possess something that acts like a protective mechanism and prevents or delays the union of antigen with the cells of the body, and thus limits or makes impossible the formation of precipitins. The results also indicate that when precipitins in high titer are produced, the precipitinogen disappears promptly, and that when there is little or no precipitin formation the precipitinogen persists.

Urea Excretion

DRS. J. HAROLD AUSTIN, EDGAR STILLMAN and DONALD D. VAN SLYKE, New York: In using the rate of urea excretion as an index of kidney capacity, there are certain factors besides the functional capacity of the kidneys which influence the urea excretion rate to such an extent that they must either be kept constant or be allowed for by calculation, before the excretion rate of urea can be taken as even an approximate measure of the functional capacity of the kidney. One of these factors is the concentration of urea in the blood. Contrary to the view of Ambard and in accordance with the observations of Marshall and Davis, we find in dog and in man that, other factors being constant, the rate of urea excretion is directly proportional to the concentration of urea in the blood, and not proportional to the square of the latter.

On the basis of our own observations on normal human subjects, and of those of McLean and Addis, we find that the ratio of urea excretion to blood urea concentration varies considerably in the normal subject. These variations cannot be explained by variations in the concentration of urea in the urine. A constant relation has, however, been observed between these variations and changes in the rate of urine volume output. The relationship that holds may be thus expressed:

$$\frac{D}{W} = K B \sqrt{\frac{V}{W}}$$

D, grams of urea excreted per diem, calculated from seventy-two minute period.

B, grams of urea per liter of blood.

V, liters of urine excreted per diem calculated from seventy-two minute period.

W, body weight in kilograms.

In all observations on normal human subjects as published in the data of McLean and Addis and in our own observations, the value of *K* is 7.5 ± 3 .

The influence of increasing the rate of urine volume output on the rate of urea excretion holds, however, for all normal subjects studied only up to a certain limit, which we call the "augmentation limit," which appears to be characteristic for the individual, and which has in our experience been between the rates of 3 and 5 liters per diem. Beyond this "augmentation limit," the limit is to be used as *V* in the formula in place of the urine volume output observed.

For the calculation of the daily rate of urea or of urine volume excretion from urine collected during a short period of time, it has been found desirable in many instances, when the normal daily output of creatinin for the individual in question is known, to calculate the rate of excretion from the ratio of the creatinin contained in the sample of urine collected to the total daily excretion of creatinin for that individual.

Site of the Cardiac Lesion in Two Instances of Intraventricular Heart Block

DRS. B. S. OPPENHEIMER and H. E. B. PARDEE, New York: The hearts of two patients were examined in order to locate the site of the lesion associated with electrocardiograms suggesting partial block of either the right or the left branch of the auriculoventricular system. As the main deflections in the two sets of electrocardiograms were in opposite directions, it was to be expected that the lesions, if any, in the two instances, would be found on opposite sides of the heart. There has been considerable theoretical discussion as to which type of electrocardiogram is associated with right-sided and which with left-sided block. The first case showed electrocardiographically a main deflection inverted in Lead I, upright on Leads II and III, a marked widening of the foot-points of the Q. R. S. complex and only moderate voltage; in addition, there was auricular fibrillation. Microscopic examination of serial sections of the auriculoventricular system revealed that the right bundle branch became attenuated almost immediately after its origin from the main stem, and was surrounded by connective tissue. This diminution became more pronounced, until at a distance of 7.5 mm. from the bifurcation, scarcely one or two doubtful muscle fibers could be seen. Below this the right branch increased in size again, until at 4 cm. below the bifurcation it was of normal dimensions. There was marked fibrous myocarditis of the septum, involving chiefly the left side, especially the subendocardial region. The left branch presented no lesion. In the second case on two examinations at an interval of six weeks, electrocardiograms revealed that the main deflection was upright in Lead I and inverted in Leads II and III, and that it was notched, the foot-points being abnormally separated. Wave P was present throughout. Serial sections showed the auriculoventricular node, stem and right branch intact. The left bundle branch was embedded in dense fibrous tissue throughout its course, and at a distance of 3.5 cm. below its origin, its posterior (dorsal) half was replaced by connective tissue continuous with an adherent, organized mural thrombus. In addition, there was a general fibrous myocarditis, which predominated on the left side only.

The direct application of the published electrocardiograms associated with experimental bundle branch lesion in dogs to the interpretations of bundle branch block in man is rendered doubtful by certain anatomic peculiarities of the dog's heart and its relation to the thorax. In view, therefore, of the pathologic findings in these two human cases, it seems that the usually accepted electrocardiographic interpretation of right and left bundle branch block in man may possibly have to be revised.

Study of a Case of Low Carbon Dioxid Combining Power of the Blood

DRS. O. H. PERRY PEPPER and LEON JONAS, Philadelphia: A young man, aged 16, who entered the University Hospital complaining of shortness of breath and a feeling that his heart beat fast, four weeks before admission, while in good health but without previous training, had run for over an hour, "at least 5 miles." Three days later he became conscious of the beating of his heart. Still a week later he had an attack of dizziness and vomiting which lasted for two days. He asserted that he lost ten pounds in the last two weeks. He had not been well since the overexertion in running. His previous medical history was negative, nor was there anything of importance in the social and family history. The boy was a marked mouth breather; the breathing was very deep and the rate more rapid than normal, from 24 to 32 per minute. The hands and fingers were cyanosed, the blood pressure low and the tonsils enlarged. Repeated examinations of the heart by several examiners, by fluoroscopy and by electrocardiography revealed no alteration from the normal. The lungs, also, were normal. The Wassermann reaction and blood count were normal. Neurologic examination was negative. Because of the respiratory behavior, the laboratory was requested to determine whether or not an acidosis was present. Examinations revealed the blood carbon dioxid combining power to be 29 per cent.

by volume, and persistently remained between this figure and 50 per cent. by volume. The urinary urea nitrogen and the titratable acidity were always within normal limits. This unexpected low figure could not be explained on a diabetic basis, as the blood sugar was 0.1 per cent. after starvation, and the urine was always free of sugar and ketones.

It was not felt that renal involvement was the cause, because frequent blood urea nitrogen determinations were always below 15 mg. per hundred c.c. The phenolsulphonephthalein elimination was constantly normal. Urinary analyses occasionally revealed a trace of albumin and a few casts; a marked polyuria occurred at times, although the urine could be easily concentrated to less than 500 c.c. per twenty-four hours and the specific gravity raised to 1.029.

In order to determine whether a hypersensitive respiratory center might not be the cause of the low carbon dioxid combining power through overventilation, the rebreathing of increasing amounts of carbon dioxid was resorted to, but with negative results. Under the influence of morphin the rate and depth of respiration were markedly reduced and the carbon dioxid combining power raised, only to relapse after the influence of the morphin had ceased. In view of these various investigations, the low carbon dioxid remains unexplained.

Studies in Sugar Tolerance

DR. W. R. OHLER, Boston: One hundred and fifteen glucose tolerance tests were made at the Boston City Hospital according to the technic of Janney and Isaacson. Of the entire group, a small group of eleven is here presented for discussion. All of these cases were referred to the diabetic clinic with a diagnosis of diabetes based on the finding of sugar in the urine, in amount varying from a trace to 1 per cent. One patient gave a history of diabetes in father and grandfather; three a history of thirst and polyuria; four had been told by family physicians that they had diabetes; one had been discharged from the army because of diabetes, and two were unaware of any metabolic disorder.

Tolerance tests were made because of the absence of hyperglycemia, and because glycosuria was not always present, even on an unrestricted diet. The results of the tolerance tests were as follows: 1. Glycosuria was present in nine of the eleven cases at the end of the two-hour period. 2. One case gave a so-called typical diabetic curve. 3. Four cases gave curves that were not typical of diabetes but which were distinctly abnormal in that the readings went over 0.16 per cent. at the end of one hour and did not return to within two points of the fasting figure at the end of two hours. 4. Six cases, including the two that did not have glycosuria, gave curves very similar to the curve given by a normal adult.

Comment: 1. Are these cases to be considered true diabetes or so-called renal diabetes? The one patient showing a typical diabetic reaction undoubtedly had true diabetes, despite the fact that glycosuria is not always present on an unrestricted diet. The four cases presenting distinct abnormalities in the curve may represent a transitional stage in the development of the disease, the onset of which we know to be insidious. The six cases giving practically normal reactions, except for the presence of glycosuria in four of the group, may or may not be true diabetes. One case is presented in which a second tolerance test had been made after an interval of nine months on an unrestricted diet. The only striking difference between the two curves was a rise in the fasting blood sugar from 0.06 to 0.09. The answer to the foregoing question can be given only after a long period of observation. 2. There are probably many more such cases in existence than have been previously pointed out. Glucose tolerance studies in such cases add greatly to our knowledge of the diagnosis and development of the disease. 3. It is quite possible that some cases of diabetes which have shown remarkable progress as measured by glycosuria and hyperglycemia readings may belong to a group of the sort here presented. 4. Abnormal glucose tolerance curves are found in a variety of clinical conditions in which there has never been any question of diabetes. In drawing conclusions from glucose tolerance studies, one must be careful to eliminate other conditions that may influence the results.

Review of Literature of Past Five Years on Anaphylaxis and Related Phenomena. A. R. Cunningham, Boston.—p. 392.

Scorbutic Beading of Ribs.—According to Hess and Unger, beading of the ribs, the so-called rachitic rosary, should not be regarded as pathognomonic of rickets. It occurs very frequently in connection with infantile scurvy and is one of the typical signs of this disorder, developing in the course of the disease, and disappearing rapidly with the recession of the other symptoms when an antiscorbutic foodstuff is given. This is borne out by clinical observations on man and on animals, as well as by postmortem examinations.

Prenatal Syphilis.—Kolmer believes that it is proper to regard all children as syphilitic when born of parents one or both of whom react positively to the Wassermann test, even though both child and parents are clinically free of the disease, and even to institute specific treatment as a precautionary measure, and especially if such children are manifestly below par in weight and nutrition.

Growth Stimulating Properties of Orange Juice.—The results obtained by Byfield and his associates by the addition of orange juice to or omission from the diet of babies were uniform and constant. Under the conditions maintained, growth, as evidenced by the weight curves, was in all cases stimulated when orange juice was given. On the other hand, orange juice from which the antineuritic vitamin had been removed was without influence.

Fluid Injections in Dehydrated Infants.—The effects of introduction of fluids in the case of dehydrated infants were studied by McLean and Lang. Only infants showing signs of dehydration were given treatment. Seventy-six infants received 269 injections of fluid. Of these, 155 were hypodermoclyses; ninety-two were intraperitoneal injections, and twenty-two were sinus injections. The mortality among these seventy-six cases was 56.6 per cent. The amount of the clyses varied between 90 and 150 c.c., depending on the size and the condition of the child. The following solutions were used: 6 per cent. dextrose in physiologic sodium chlorid solution; 6 per cent. dextrose in distilled water; physiologic sodium chlorid solution; 2 per cent. sodium bicarbonate with 1 per cent. dextrose solution. Among the special effects were the following: The pulse is more frequently affected after sinus and intraperitoneal injections than after hypodermoclyses. The respiratory rate is more frequently affected in peritoneal injections than in sinus injections and hypodermoclyses. The temperature is more frequently elevated in sinus injections than in intraperitoneal injections or hypodermoclyses. Weight gains are more frequently noted following intraperitoneal injections than after sinus injections or clyses. Certain infants show no improvement until after repeated injections. The shorter the interval between the onset of symptoms and the beginning of treatment, the greater the response.

Length of Intestine in Children.—The length of the large intestine in young children Robbin found was between 80 and

130 per cent. of the length of the body in 91.3 per cent. of 185 bodies of infants examined. The length of the small intestine was found to be between 500 and 900 per cent. of the length of the body in 79.9 per cent. of all cases. An unusually long large intestine was not accompanied by an unusually long small intestine; an unusually short large intestine was not accompanied by an unusually short small intestine. No association of an unusually short or long small or large intestine with the clinical condition could be established. That the anomaly of an unusually long large intestine might be a potential factor in the causation of chronic intestinal indigestion or chronic constipation of later life is worthy of consideration. The indications are that during early life the body grows somewhat more rapidly in length than does either the small or large intestine.

Treatment of Birth Fractures.—Six cases are cited by Boorstein. They show that the Thomas Jones splint can be used with safety in cases of birth fractures affecting the femur or the humerus. It allows easier transportation, permits cleansing of the children and saves a great deal of watching. It permits early massage. The deformity is easily controlled. The union probably occurs earlier on account of the ability of the infant to use the limb, to elevate it together with the brace.

Craniotabes and Beading of Ribs in Rachitis.—Among 4,944 children examined by Schwarz, 734 showed craniotabes some time during the first year, and 301 had evidences of these soft spots during the first months of life. This number decreased regularly as the infants grew older. Thirty-five per cent. of all the children presented beading of the ribs, 13 per cent. during the first month of life, and this proportion changed very little throughout infancy, perhaps becoming slightly less at an age when rachitis is more common. Schwarz is sure that nearly all infants, if examined regularly throughout the first year, will present this condition in a greater or less degree at some time or other in their infancy.

Inspiratory Movements of Costal Margins.—In interpreting the inspiratory movements of the costal margins, Hoover says, one must study the symmetry and asymmetry of not only the entire costal margins but of the inner and outer portions of each costal margin. Movements of the costal margins are modified with changes in the curve of the plane of the diaphragm, by paresis of either the diaphragm or the intercostal muscles, and by synechia between the diaphragm and the thoracic wall. Such studies improve the accuracy with which one differentiates between infraphrenic and supraphrenic disease, and enable one also to estimate the conformation of the heart and the size of the pericardial sac and to differentiate between lesions which cause phrenic displacement and those which do not modify the place of the diaphragm.

Pathology of Gallbladder.—The stimulation of greater interest and more detailed research in conditions of the bile

passages which have heretofore been mistaken for normal is the object of this paper, which is based on an examination of 4,998 gallbladders, of which 4,824, or 96.5 per cent., showed gross pathologic lesions.

Chronic Appendicitis and Continued Ill Health.—Gibson suggests that the presence of other undiscovered lesions may often account for continued ill health after appendectomy. Therefore, it is advisable to make a good sized incision, and, even if a frankly pathologic appendix is found, look for other possible lesions, and if no obviously pathologic appendix is found until every other possibility has been exhausted, making a supplementary incision, if necessary.

Gastric Secretion in Neurocirculatory Asthenia.—Musser has found that in patients suffering with neurocirculatory asthenia there is a very definite increase in the total acidity and the free hydrochloric acid as compared with controls. These figures do not represent abnormal hyperacidity. They do show, however, that almost uniformly soldiers suffering with neurocirculatory asthenia as contrasted with apparently normal soldiers, both eating the same food, under identical routine and under the same conditions of living, show a higher gastric acidity. This is a diagnostic point which may be of value in differentiating the disorder in questionable cases. It seems to add further evidence to that already accumulated that these soldiers are suffering from a neurosis with which is probably associated a hyperirritable vagus.

Pathogenesis of Empyema.—In Moschowitz' opinion, empyema in most instances results from the rupture of a small subpleural pulmonary abscess. An empyema is the final stage of a process in which the first stage is a serous pleurisy and the second a seropurulent pleurisy. The latter is the so called "formative" stage of an empyema. The "formative" stage is unaccompanied by pleural adhesions. The stage of final empyema is always accompanied by adhesions. The vast majority of empyemas are of the encapsulated variety. Very few occupy the entire pleural space. Metastatic suppurations accompanying empyema are to be found rather as complications of the causative pneumonia than of the empyema. Moschowitz outlines in detail the treatment he employs at various stages.

Rheumatic Fever.—In a series of seventy-three soldiers with acute rheumatic fever, 51 per cent. gave a previous history of rheumatic fever and 40 per cent. showed large or ragged tonsils. The joints involved in order of frequency were knee, ankle, shoulder, wrist, foot, elbow, hand and hip. Acute pericarditis was found in 10 per cent. of the cases, usually very transient. Acute pleuritis was found in 19 per cent. There was evidence of mitral endocarditis in 40 per cent. of the cases; mitral and aortic endocarditis combined in 8 per cent. Most of these cases were apparently of long standing. Acute temporary heart block was discovered in 4 per cent. of the cases. Response to forced salicylate therapy was very striking. It seemed that the course of the disease was shortened by salicylates.

Fibrinuria in Kidney Carcinoma.—O'Connor reviews twenty-five cases recorded in the literature and adds one personal case. He claims that the fibrin found in the urine in these cases was not a product of the carcinoma itself, but a result of the associated renal destruction. The pathologic condition underlying the etiology of this condition seems to be a nephritis of varying grade and severity.

*Congenital Cystic Kidney: Report of Case. H. Green, Boston.—p. 614.

Hip Joint Disease in Children.—The points on which Legg insists are: A more careful history should be obtained; a more complete physical examination should be made; a roentgenogram should be made in every case of suspected bone or joint disease, and every laboratory method should be used before making a positive diagnosis. He emphasizes the extreme importance of early differentiation whenever possible.

Perforation of Cecum.—An entirely sloughed-off gangrenous appendix, with a perforation of the cecum 1.75 cm. in diameter was found in Risley's case.

Congenital Cystic Kidney.—The records of the Children's Hospital, Boston, contain only three cases of congenital cystic kidney. Greens' patient was 2 years old. The child had spells of "getting blue," coming usually in the morning. He had them every day for a week, usually lasting fifteen minutes. The mother had also noticed a yellowish-white discharge on the diaper. The urine had been dirty white. Eyes had been puffed, but the mother had noticed that the body was swollen. The child died and at necropsy both kidneys were found lobulated and cystic.

Experimental Pneumococcus Meningitis.—The experiments reported on by Idzumi show that pneumococcus cerebrospinal meningitis may be produced in rabbits by injecting virulent cultures directly into the subarachnoid of the spinal cord. The reaction is much less marked in dogs, and usually takes

the form, of hyperemia without well defined suppurative changes, owing to the high resistance of this animal to the pneumococcus. The intravenous injection of virulent pneumococci was not followed by the development of meningitis. The intravenous injection of these virulent pneumococci into rabbits, followed by spinal puncture and the subtheal injection of sterile broth and serum, was usually followed by the production of acute meningeal congestion and occasionally by suppurative leptomeningitis. In dogs there was invariably acute congestion with no evidence of suppurative changes. The subtheal injection of virulent pneumococci into the lumbar region of the spinal cord of rabbits is usually followed by the development of a fatal suppurative leptomeningitis accompanied by definite changes in the tissues and spinal fluid, fever, leukocytosis and clinical symptoms of meningitis, such as hyperthesia, opisthotonos and convulsions.

Studies on Diphtheria Bacillus.—By the use of the agglutination test two groups of the diphtheria bacillus have been determined. These groups are distinct, showing no evidence of cross agglutination. The members of the two groups show no differences in morphology or in relative virulence. Evidence is presented by Havens showing that the antitoxins of these groups are not so sharply differentiated as are the agglutinins. Group antitoxins seem to exist in small amounts common to both groups. Havens suggests that the effectiveness of therapeutic diphtheria antitoxin could probably be enhanced by the inclusion in its production of a member of the second or smaller group.

New Influenza Coccus.—Tunnickliff has isolated a peculiar green producing coccus from the edematous brain in influenzal bronchopneumonia, and generally in pure culture. In no instance was the Pfeiffer bacillus cultivated from the brain. The serum of rabbits immunized with strains of this coccus from influenza and its complications contained opsonins and agglutinins for other similar, bile insoluble influenzal cocci, and also for certain influenzal cocci, which were bile soluble and agglutinable by antipneumococcus serums. These results indicate that the green producing influenzal cocci form a group, the members of which are closely related immunologically. The results of absorption experiments with reference to agglutinins also suggest that this is a group of closely allied organisms. Immune rabbit serum treated with the homologous influenza coccus lost its agglutinins for the homologous coccus and for allied influenzal cocci. Absorption with allied influenza organisms also removed the immune bodies for the homologous coccus as well as for the closely related cocci, but absorption with pneumococci of Types 1 and 2 not of influenzal origin, did not remove the agglutinin for the influenza cocci.

Effect of Leukocytic Extracts on Leukocytes.—The results of Tunnickliff's experiments show that the subcutaneous injection of leukocytic extract in rabbits produces an appreciable increase in the number of leukocytes in the circulating blood lasting from one to four days. The leukocytes set free by the extract possess considerably more phagocytic power than normal leukocytes. While the intravenous injection of leukocytic extract produces a more rapid rise in the number and activity of the leukocytes, the duration is shorter than that produced by subcutaneous injection. Leukocytic extract appears to exert no influence on the leukopenia produced by benzene.

Immunity in Influenza.—The results reported by Jordan and Sharp indicate that no marked immunity exists from twelve to fifteen months after a previous attack. They do not show that some degree of immunity may not obtain at an earlier period.

Radium Treatment of Uterine Hemorrhage.—Certain disagreeable sequels from intra-uterine radiation are reported by Graves. Though mentioned by several writers they have received minor attention or have been lost sight of in the reports of brilliant end results. Some of these symptoms are significant chiefly from the psychologic influence which they may exert on the patient, but even these may be of considerable import to the patient's general welfare. The symptoms are nausea, continuation or reappearance of the bleeding, for the cure of which the operation was undertaken, leukorrhea, pain, acute nephritis and nervous symptoms. Graves warns those who have not yet used radium in the treatment of nonmalignant uterine hemorrhage that the immediate convalescence from a given treatment is by no means always a bed of roses. Radium is a powerful and dangerous agent, and in certain cases, not always recognizable. Its use is attended with the gravest risks. The possibilities of radium for harm have not been sufficiently exploited in the literature, and it is the duty of those who are using it to spread the propaganda of caution, in view of the general and, perhaps, indiscriminate distribution which radium is inevitably soon to enjoy.

Endocrine Therapy.—To illustrate the action of thyroid in its protective rôle over the renal epithelium, two cases are reported by Bandler. Observation and therapy have convinced him also that the pituitary, particularly the posterior lobe, plays the most important rôle in fibromyomata of the uterus.

Pregnancy in Advanced Cancer of Cervix.—Shoemaker's patient was 47 years of age, para VII, who was brought in by ambulance when actually in labor, with a history of pulmonary tuberculosis and asthma of long standing. There had been no early symptoms of pregnancy. For six months there had been irregular uterine hemorrhage and increasing abdominal enlargement, with loss of weight. Within two days the hemorrhage had been extreme, requiring packing by her physician. There were labor-like pains, chills, temperature of 102 F., pulse 124, leukocytosis 28,000, rising to 32,000. Apparently the membranes had ruptured within twenty-four hours. The diagnosis was pregnancy with dead child; epithelioma of cervix. A craniotomy was done, the body of the child delivered and the uterus packed. At the end of three

weeks, the patient was out of bed, eating a full diet, with no soreness or pain, very slight vaginal discharge, no bleeding. As radical operation for removal of the disease is out of the question, the future treatment will be palliation with radium.

Vesicovaginal Fistula.—According to Judd all vesicovaginal fistulas should be considered operable as long as the sphincter muscle of the bladder is intact or can be repaired. If the sphincter has been completely destroyed it will be necessary to consider some other procedure. Suprapubic extraperitoneal operations seem to be indicated if the cystoscopic examination reveals injury to a ureter as well as to the bladder, or it may be indicated if the fistulous tract is adherent to the pubic bone. The plastic vaginal operation consists in completely separating the bladder from the vagina, and closing the two separately and obliterating all dead space. A large percentage of complete and permanent cures follow such operations.

Congenital Occlusion of Duodenum.—Freeman has operated in six cases of partial occlusion of the duodenum at the duodenojejunal angle, simulating pyloric obstruction, which occasionally occurs from the persistence of a condition normally existing in fetal life. In this, the duodenum, instead of appearing in the abdominal cavity from beneath the transverse mesocolon to the left of the spine, as it should, emerges to the right, its transverse and ascending portions possessing a peritoneal covering and mesentery of their own, similarly to the rest of the small intestine, instead of being fixed in fibrous tissue, as is normally the case. At the duodenojejunal angle, however, the bowel is hung up to the root of the colonic mesentery by a firm adhesion (duodenal fold of fetal life), the "kink" thus produced being intensified by the downward pull of the free duodenal loop. This kink is deeply situated and in freeing it care must be taken not to injure the bowel, the inferior mesenteric vein or the left

colic artery. A considerable denudation of the gut may be necessary, which should be covered either by reuniting the peritoneum or by means of a free omental graft.

Recurrent Bladder Calculi and Diverticulum.—The case reported by Davis is of unusual interest, in that the recurrent vesical calculi were associated with a residual urine due to a contracture of the vesical orifice, and in that it was definitely shown that the recurrent vesical calculi formed in turn on a spicule projecting into the bladder from a calculus contained in a diverticulum.

Syphilis and Pregnancy.—A routine Wassermann test made by Young on twenty-five pregnant women was positive in about 25 per cent.; of these 18.7 per cent. were either 3 plus or 4 plus.

Cholecystectomy.—Yates describes a submucous separation of the gallbladder and cystic duct from the serosa and subserosa largely by blunt dissection.

*Case of Hirschsprung's Disease in Old Age. J. Ueda.—p. 2.

Death from Syphilis of Heart.—A man, aged 24, fainted with symptoms of angina pectoris, and died suddenly, while undergoing strenuous muscular exercise, three years after contracting syphilis. At the postmortem two gummas were found in his heart, one situated in the auricular septum, and the other in the aortic orifice and its connecting part with the ventricular septum. The latter pressing on the left coronary artery caused the formation of cicatricial tissue in the posterior wall of the left ventricle near the apex and among posterior papillary muscles. The cause of the sudden death was presumed to be extravasation in the gummas, resulting from muscular strain and followed by total compression of the left coronary artery.

Hirschsprung's Disease in Aged.—Ueda's patient was aged 61. He had suffered from Hirschsprung's disease since the age of 57.

"Concentrating" and "Centrifugal" Vibrations. E. F. Cyriax.—p. 165.

Diffuse Symmetrical Scleroderma.—The mode of onset of Henderson's case with muscular and articular pains, is quite in accord with classical descriptions of the disease. The deformities produced in the hands, as the disease progressed, strongly resembled those of rheumatoid arthritis. The steadily progressive character under observation was very striking, despite nourishing diet, tonics, and abundant lubrication of the skin. The very remarkable degree of emaciation reached before death is of itself almost unique. Some idea of the extreme degree of emaciation may be derived from the following measurements taken a few days before death: neck, 9 inches; chest, 24 inches; waist, 18 inches; hips (around), 26 inches; upper and forearm (maximum),

4½ inches; thighs (maximum), 8 inches; calves (maximum), 6 inches. The patient weighed 54 pounds. The mode of death by intercurrent complication is usual, but the exact nature of the pulmonary condition was rendered doubtful by the scarcity of physical signs, the absence of spit, and the scanty degree of febrile reaction. No lesion was found to shed any light on the cause of such a marked condition.

Sodium Hydnocarpate and Sodium Morrhuate in Leprosy.

—The results obtained from the use of sodium hydnocarpate, and sodium morrhuate in the treatment of 300 cases of leprosy are analyzed by Muir. These cases were of the anesthetic, mixed and nodular types, 179, 81 and 40 cases, respectively. The dosage of both drugs varied from ½ c.c. to 5 c.c. of a 3 per cent. solution, beginning with the smaller dose and gradually increasing to the larger. Injections of hydnocarpate were chiefly given intravenously and the morrhuate was given hypodermically or intramuscularly, and in some cases intravenously. Of the patients treated with hydnocarpate, there was improvement in 132, and much improvement in fifty-eight. In several cases the lesions disappeared entirely. With sodium morrhuate no patients were recorded as being worse, 33 were not improved, 48 were slightly improved, and 36 were much improved. Thus 71 per cent. showed some measure of improvement, of which 31 per cent. showed much improvement. The opinion is that the best results are obtained in anesthetic cases with sodium hydnocarpate, but that the veins soon become blocked, and that sodium morrhuate has then to be resorted to as it can be given hypodermically and intramuscularly. In nodular leprosy sodium morrhuate does not appear to be in any respect behind sodium hydnocarpate, and it has the advantage that it may be injected in small doses into the nodules where it acts locally on the bacilli, causing first a swelling of the nodule infiltrated and thereafter a shrinking and softening, while the local lymphatics become temporarily red and swollen.

Morrhuate in Leprosy and Tuberculosis.—Rogers has recently been giving an ethyl ester morrhuate in both leprosy and tuberculosis by the subcutaneous method with very little trouble to the patient and apparently distinctly favorable results, although much further experience will be necessary before the exact value of the new preparation can be decided.

Gynocardate and Morrhuate in Leprosy.—Neve's investigation shows that on an average treatment of six months about half the patients appear to derive benefit from the gynocardate and morrhuate treatment. Those not definitely improved appear to remain stationary. Only about 10 per cent. show fresh manifestations of disease while under treatment, some of which have been due to the freeing of toxins by overaction of the drug. Laryngeal and ocular leprosy require great caution in the exhibition of these remedies.

Sodium Morrhuate in Tuberculosis.—Ganguli is thoroughly convinced of the value of sodium morrhuate treatment in pulmonary tuberculosis. It was noted that in cases where intravenous injections were given, the results were far more satisfactory than those obtained by the subcutaneous method. Rogers' directions were strictly followed, beginning with ½ c.c. of a 3 per cent. solution, gradually increased by ¼ c.c. once or twice a week up to 2 c.c. after which doses were

increased by ½ c.c. weekly till the maximum of 4 c.c. had been reached. Besides bacteriolytic action as shown first by beading and then disappearance of the tubercle bacillus from the sputum, there is some fibrolytic action marked in cases where sodium morrhuate has been tried.

Mutton Fat as Vehicle for Emetin Bismuthous Iodid.—The problem of finding a vehicle for this drug which would pass through the stomach unchanged and be digested by the intestinal juices, was solved by Mayer by rubbing up the drug with sixteen parts of mutton fat, molding the mass into rounded pills of about 7 grams each in weight, and covering each with a layer of melted mutton fat applied with a paint brush. These pills pass through the stomach unchanged. The fat is solid at body temperature, is not digested until it is too far from the pyloric orifice to be regurgitated and cause vomiting or even nausea. That the drug is altered by the intestinal juices is shown by the discoloration of the feces and the cure of the dysentery in a case in which these pills were used.

- Mechanism of Postoperative Massive Collapse of Lungs. J. C. Briscoe.—p. 293.

Segmental Analgesia in Visceral Lesions.—Inflammation of any viscus induces a state of hyperalgesia in the skin supplied by the same segments of the spinal cord as the viscus. If this is true, it follows that if the nerve supply of the viscera is known, it is possible to diagnose inflammation in any viscus by demonstrating hyperalgesia in the corresponding area of the skin. The area of distribution which Jones mapped out for each segment is described in detail. The number of persons examined for the data in this paper was 1,040, of which 120 were normal men, used as controls. But many of the patients were suffering from more than one disorder, as for instance trench fever and bronchitis, or dysentery or endocarditis, so that more lesions than patients were examined. The results obtained show that segmental hyperalgesia is not universally present in visceral disease. In cases of very acute illness, although symptoms may be marked, hyperalgesia is often not demonstrable, probably because the attention cannot be concentrated. In the most favorable circumstances, segmental hyperalgesia will not be found in more than three cases out of four, and it will rarely be found in any case of very acute illness. Segmental hyperalgesia in the diagnosis of visceral lesions has considerable value in positive cases but is not infallible, and its negative value is negligible.

Anaphylaxis in Treatment of Hemophilia.—The intradermal reaction is a modified form of anaphylactic shock of general as well as of local significance, and in which the stimulation of the thrombogenic functions of the somatic cells is a salient feature. The changes in coagulability of

the blood in anaphylactic shock occur in two stages: a period of acceleration which occurs early, followed by a period of retardation; further, that the predominance of the former or the latter depends on the lesser or greater severity of the shock. The intoxicating injection in a sensitized individual may act as a catalytic agent in inducing the intracellular reactions which constitute the anaphylactic phenomena. In cases of hemophilia, Vines says, the duration of the effect of the intradermal reaction is dependent on the duration of the anaphylactic period. But the shorter or longer duration of this effect is also directly dependent on the greater or lesser severity of the hemophilic condition.

Fat Metabolism in Marasmus.—Observations made on the digestion and absorption of fats in cases of marasmus or infantile atrophy are reported by Hutchison. They show that the digestion of fats in infantile atrophy, rickets, and tetany is carried out as efficiently as in healthy children. There is a slightly greater loss of fat in infantile atrophy, due to the motions being larger than in healthy children, but the excessive loss, which amounts to 0.88 gm. per day, cannot be neglected so far as nutrition is concerned. There is no true deficient absorption. In rickets, the excess loss of fat per day over that in healthy children averages 0.6 gm., an amount which is quite sufficient to affect nutrition. In tetany, the excess loss is 2.4 gm. per day. This is due chiefly to the passage of larger motions than normal, viz. 14.4 gm. compared with 9.9 gm., and to a less extent to a true deficient absorption, since the fat in the feces averages 38 per cent. This loss is sufficient to affect nutrition. Other facts point to a normal fat absorption in atrophy, viz. the increased amount of fat absorbed with an increased intake, and the fact that improvement frequently follows the lowering of the fat content of the milk. Saponification of fats in the intestine does not affect the absorption of fats. The fairly constant percentage of fat in the feces of man and other animals suggest that fecal fat has a function to perform, and that it is not a pure excretion. There is no evidence, however, to indicate what this function is.

 *Rectocolitis of Uremic Origin. R. Bensaude and others.—p. 41.
 *Bronchopulmonary Spirochetosis. M. Salomon.—p. 53.

The Blood Pressure in Tuberculosis.—The results of the research reported indicate that when the systolic, the maximal, arterial tension is normal, or even slightly above normal, in chronic pulmonary tuberculosis, the trend of the disease is toward recovery, or at worst the course is very slow. With a low systolic pressure, a favorable course is the exception. The minimal or diastolic pressure does not vary much from normal. The arterial tension cannot be estimated by a single examination; several readings are required, the tests made all under the same conditions.

The War and Pulmonary Tuberculosis.—Bernard and his co-workers analyze conditions in 872 cases of pulmonary tuberculosis in soldiers some of whom had been on active service at the front for nearly the entire war. They could not have stood the strain of the campaign for so long if they had not been sound to begin with, and the disease got a foothold in them as the direct consequence of the war conditions at the front. These vigorous men were "wounded" by the tubercle bacillus just as surely as their mates were wounded by the enemies' projectiles.

Hemorrhagic Rectocolitis of Uremic Origin.—Bensaude, Cain and Antoine refer to dysenteriform enteritis in the course of acute and chronic uremia. In a case reported, with the microscopic findings, the woman's mental confusion, the dysenteriform stools with red blood and the intense albuminuria and terminal coma were explained by the pronounced atrophy of both kidneys and adenomatous condition of the suprarenals. Nearly all the organs showed congestion and

hemorrhages, most pronounced in the lower bowel—all evidently of toxic origin. In a second case, hypertrophy of the prostate had induced retention, distention of the bladder and nephritis, the consecutive uremia causing intestinal hemorrhages, but there was no ulceration; the lesions in the intestines were exclusively mechanical, and they were found throughout the entire digestive tract from stomach to anus. Instead of ascribing the blood in the stools to hemorrhoids, the rectoscope will reveal the toxic injury of the intestine.

Bronchopulmonary Spirochetosis.—Salomon gives a critical review of the literature on this subject since Castellani's first report in 1904. The disease has been reported from most parts of the tropics, from Missouri, Ohio, Switzerland, Italy, and in 1918 was noted in France. The spirochetes in the sputum can be readily seen with the dark field, and the disease is highly contagious. The diagnosis is based usually on the discordance between the profuse and protracted, blood stained expectoration and the relative mildness of the auscultation findings. No fatal pure case has been recorded as yet; the subacute cases keep up usually for two months, and the chronic for years. Isolation is indispensable not only to protect others but to protect the patient against superposed infection which is liable to be particularly injurious. In treatment of the chronic form, general hygiene and fresh air, arsenic and other tonics are useful, supplemented by some form of arsphenamin by the vein, especially in the fetid and gangrenous cases. Intratracheal injections or inhalations of balsamics might be tried as also intramuscular injections of iodopin as recently recommended by Najib Farah.

Paris Médical, Paris

 Case of Pulmonary Mycosis. Jourdan.—p. 326.
 Open Plaster Jacket. L. Thyss-Monod and G. Monod.—p. 328.

Amblyopia from Poisoning with Carbon Disulphid.—The two men were employed in making commercial mustard plasters, the mustard being spread on a base of a solution of rubber and carbon disulphid. After doing this work through the hot weather in a poorly ventilated workroom, both developed bilateral central scotoma with considerable restriction of the visual field, the clinical picture of alcohol or tobacco retrobulbar axial neuritis. The scotoma was more extensive than with alcohol or tobacco poisoning, and objects were seen as through a veil. The poisoning may induce general symptoms, besides, vomiting, colics and nervous disturbances, dizziness and delirium, and sensations of chilliness and of electric currents, especially in the arms, tremor and even paralysis. In the cases on record, recovery ensued in 33 per cent. and improvement in 25 per cent. In the two cases reported here, there has been no improvement in the impaired sight during the three months to date. Intoxication occurs by inhaling the vapor. Treatment may include strychnin and weak doses of iodids, diaphoresis, steam baths and infusions of jaborandi. Ample ventilation of the workrooms is imperative.

Pulsation in the Aorta Above the Sternum.—Babes and Dumitresco refer to pulsation in the aorta when the finger is worked down between the two sternocleidomastoid muscles where they join the sternum. The pulse beat is vertical and strong, and in 500 persons examined they found this pulsation not only with dilatation of the aorta but also whenever the heart was pushed up toward this region by hypertrophy of the left ventricle or by pressure in the chest or abdomen from pericarditis with effusion, ascites, abdominal tumor or great enlargement of the liver.

Induced Fistulization of the Trachea.—Rosenthal comments on our inconsistency as we do not hesitate to do tracheotomy at once when an acute throat trouble threatens suffocation, but we seldom think of doing this when the throat disease is slowly progressive although the ultimate outcome is the same suffocation in both. With tuberculosis of the larynx, he advises an early small opening into the trachea, a mere fistula, with a miniature tracheotomy tube. He introduces first a curved needle, only 6 or 7 mm. in diameter, in the

cricothyroid space. The curving of the needle prevents injury of the posterior wall of the larynx, and it permits local medication. He follows this with the tracheotomy tube; the diameter of the tube is child's size for an adult, although the outside portion is standard adult size.

*The Blood Pressure and the Gallop Sound. A. Amblard.—p. 263.
*Plurality of Spirochetes of Syphilis. P. Pagniez.—p. 266.

The Saliva in Diabetes.—Rathery and Binet present evidence that the salivary glands are involved in the production of diabetes; sugar may be eliminated in the saliva as well as or in the place of its elimination in the urine. They noted elimination of glucose under pilocarpin in the saliva of a dog, after pancreatectomy, that had 3 gm. of glucose per liter of blood. Ferrannini has reported the case of a man of 70 with grave diabetes but no sugar in the urine. There was a constant flow of saliva, to a total of several liters a day, and it contained from 1 to 2.5 per cent. glucose. On an antidiabetic diet the secretion of saliva returned to normal and the sugar disappeared from it. Pellegrino has also published a case in which glycosuria alternated with sialorrhea, with much sugar in the saliva.

The Gallop Sound.—The midsystolic and the presystolic gallop sounds, with their different mechanisms and origins, both indicate that the heart is weakening. They appear as the blood pressure rises and disappear as the maximal pressure drops. With the midsystolic gallop sound, phosphorus, strychnin or spartein should be pushed to tide the myocardium along until it has regained strength. The high blood pressure is not permanent. The presystolic gallop sound is heard with permanently high blood pressure, and this has to be combated with venesection, diuretics, purges, and dieting, and the weak heart must be sustained with digitalis and absolute repose. Digitalis is required whenever the ear or the hand detects a tendency to the presystolic gallop after a test exertion.

Plurality of Syphilis Spirochetes.—Pagniez reviews recent research by Levaditi and others which is rendering more and more plausible the assumption that the spirochetes which induce cutaneous syphilitic manifestations, the dermatropic, are a different strain from those which induce general paresis. Animals inoculated with the one can develop a new primary chancre when inoculated with the other. The dermatropic strain after passage through rabbits continues to be pathogenic for monkeys, while the neurotropic loses its virulence for monkeys after a single passage through a rabbit. The neurotropic virus was applied to a scarification on the arm of a man who volunteered for the purpose, but there have been no local or general symptoms during the months since, while the dermatropic virus got into a scratch on the hand of one of the workers and induced a typical chancre with positive Wassermann reaction. A rabbit that had recovered from a dermatropic chancre was inoculated in one testicle with the dermatropic and in the other with the neurotropic virus; the latter alone developed a chancre. Virus from persons with general paresis behaves quite differently from the virus from skin lesions. A number of instances are cited in which persons infected from the same source all developed general paresis in the course of time. In the experiments in animals, the dermatropic incubation period was about six weeks; with the neurotropic, four months, and the lesions presented quite a different aspect.

Electric Tests of Sensibility of the Skin.—Neri remarks that although electric tests of the sensibility of the skin are not particularly instructive in normal conditions, in pathologic conditions they reveal characteristic changes of great importance for the diagnosis and progress of the case. He prefers the unipolar Erb electrode; this reveals the differences between the two halves of the body, the sensation just below the sensation of pain, in examining organs and individual nerves, in connection with the conductivity of the nerve. Several illustrations are given showing the more important points. In conclusion he emphasizes the possible medicolegal importance of the findings, confirming or refuting the subjective claims. With central lesions he always found complete parallelism between the afferent tracts and the sensitive organs.

He insists that perfect anatomic reconstruction is mainly the result and not the cause of perfect recovery of function.

Policlinico, Rome

March 29, 1920, 27, No. 13

- *Present Status of Vagotonia. P. Alessandrini.—p. 379.
*Eruptive Disease. D. Falcioni.—p. 385.

Vagotonia and Sympathicotonia.—Alessandrini admits that the assumption of vagotonia as opposed to sympathicotonia as the explanation of visceral neuroses has much promoted the study of neuroses. But his experience with drug tests in 100 persons has confirmed the general view that the subject is not so simple. No two of his subjects responded alike, some of the organs showing greater susceptibility than others, and the findings testifying to dissociation; some reacted alike to both epinephrin and pilocarpin; others did not respond to either. Each organ has its isolated balance, independent of all the other analogous systems in the organism. Clinical distinctions based on vagotonia and sympathicotonia are artificial.

Eruptive Disease with Rheumatoid Symptoms.—Falcioni has encountered a number of cases of an acute disease which commenced with rheumatoid pains, stomach derangement and rising temperature, and at the fourth or fifth day an intense eruption of a maculopapulous type but no pruritus; the temperature may reach 40 C., but declines as the eruption appears. The whole course of the disease is about two weeks,

and it is not contagious. Women form the main contingent, and there is always a history of overexertion or exposure. The eruption differs from those of the usual contagious eruptive diseases although there is some resemblance to the incipient stage of smallpox. In two of his cases typhus was diagnosed at first, but there was not the sudden onset of typhus nor the tendency to hemorrhage, and the nervous system did not seem to be involved in any of his cases.

Arteriovenous Aneurysm in Internal Carotid. De Raffele.—p. 345.
*Injections of Milk in Venereal Disease. M. Trossarello.—p. 350.

Influence of Diathermy on Stomach Functioning.—Setzu found that thermopenetration applied to the stomach had a constant and uniform stimulating and regulating action on both motor and secretory functioning and on the relief of pain, far beyond what can be realized with heat from without. The temperature of the stomach was raised by about 2 degrees C.

Protein Therapy in Gonococcus Infection.—Trossarello has been giving parenteral injections of milk in treatment of forty-five cases of gonococcus infection and in fifteen cases of venereal bubo. In the apyretic there is an interval of two or three hours before the chill follows the injection, and this allows ambulatory treatment as the patients are able to reach home before it. No benefit was apparent in the cases of urethritis, prostatitis, epididymitis and arthritis, but in ovarian and tubal disease marked benefit was realized. All were improved, some after a single injection. His results in these twenty cases of adnexitis surpassed, he says, those obtained with specific vaccines or antisera; the pain subsided promptly even before any objective improvement was apparent. The outcome in his fifteen cases of venereal adenitis justifies the tentative application of the simple and easy treatment to abort the lesion. He injected into the buttocks 5 or 10 c.c. of ordinary milk, at intervals of three or four days, to a total of five injections. The febrile reaction seems to be the main factor; the best results were noted in the patients that presented the strongest reactions.

Pain in the Stomach.—In this third instalment of his study of gastric pains, Rocha Vaz reviews the conflicting theories that have been advanced to explain hunger pain. His own view is that hunger pain is merely an exaggeration of the normal sensation of hunger; in his own cases of duodenal ulcer, the hunger pain occurred constantly only when the ulcer was close to the pylorus, and the stomach and the bowel below were intact. Necropsy showed ulcers in the second part of the duodenum in two cases in which there had not been the slightest symptoms from the stomach. The hunger pain with

duodenal ulcer usually merges into the pain after eating and finally into the clinical picture of stenosis of the pylorus.

Access to Foreign Body Behind the Malar Bone.—Renato Machado gives an illustrated description of the removal by way of the vestibule of the mouth of a scrap of shell close to the lower margin of the orbit, behind the malar bone.

Dysenteroid Symptoms with Inherited Syphilis.—De Medeiros' two cases warn that when the symptoms of dysentery persist unmodified by the usual measures, the possibility of syphilis should be borne in mind. One patient was a girl of 2, the other a woman of 32. The latter had had the rebellious diarrhea for three years, the stools sometimes containing blood, with no benefit from persevering antidyenteric treatment of all kinds. Improvement began at once from the first mercurial injection. The symptoms had been noted for fifteen months in the infant who had become extremely debilitated and apathetic, with ten or twenty passages a day.

Localization of Disease in the Heart. M. Arias Schreiber.—p. 102.

Tuberculous Floating Kidney.—Odriozola remarks that a floating kidney in the young should suggest possible tuberculosis. In a case reported the first symptom in the youth of 18 had been hematuria without known cause and without pain. The urine also contained much sediment. The absence of uremia confirmed further the tuberculous nature of the process. Even in advanced cases of tuberculosis the intact portions of the kidney seem to become more functionally active and thus ward off uremia.

Ascariasis.—Martínez compares four cases in adults to show the wide variety of symptoms for which the ascariasis may be responsible. Its effects are felt not only in the digestive tract but in the nervous system, although there are no pathognomonic disturbances. Even eosinophilia may be absent, and the clinical pictures are of the most varied types. In these cases the diagnosis had been a neurosis, epilepsy, essential anemia or enteritis at first. No ova could be detected in the stools, but the voiding of one or more ascarides and the subsidence of the clinical picture thereafter apparently confirmed their causal connection.

Acidosis in Children.—Torres made a special study of acidosis in children when in this country, publishing his conclusions in the *Am. J. Dis. Child.* **14**:365, 1917. He here expatiates on the exceptional frequency of acidosis in children at Bogotá, especially in infants, and its exceptional gravity, which he ascribes to racial factors, the altitude and the tropical climate. The perversion of the metabolism responsible for it may be primary from insufficiency of the liver or ductless glands, entailing overproduction of acids, or secondary to some disturbance which depletes the alkali reserves or causes retention of acids normally produced, or there may be acidosis from digestive or renal disturbance. The reaction of the blood is the only reliable criterion, and he describes the simple exosmosis test for this. The urine can be made and kept alkaline much more readily when the food contains little protein and abundance of vegetables. Normal fat and protein metabolism is contingent on keeping the digestion of carbohydrates as perfect as possible. The

uncontrollable vomiting in acidosis may entail hematemesis, and the only means to ward this off is by allowing nothing, not even water, by the mouth. We must be firm to enforce this, knowing that children have got along for a whole month without water by the mouth, when fluids were supplied by the rectum or by infusion. The needed carbohydrate is best supplied in the form of a 5 per cent. solution of dextrose by the rectum, or by the mouth in small repeated doses if the stomach will bear anything. Alkalines, sodium bicarbonate or sodium citrate can be given by rectum, vein, or subcutaneously until they can be given by the mouth. He injected 100 c.c. by the vein of a mixture of 12 gm. of dextrin; 10 gm. of sodium bicarbonate; 0.10 gm. calcium chlorid and 300 c.c. of distilled water, repeating the injection once or twice a day. In four infants less than a year old he saved two by this means, injecting the mixture directly into the longitudinal sinus at the anterior fontanel. Transfusion of blood also proved successful in one infant of 14 months. Dextrin, well boiled vegetables and skimmed milk are the main reliance as the child improves.

*Conservative Treatment of Fracture. Rauenbusch.—p. 606.
Treatment of Acute Stenosis of the Larynx. G. Zorraquin.—p. 620.

Cancer of Male Mamma.—Calcagno's patient was a man of 70 with weak heart and lungs, and he removed the malignant growth under infiltration anesthesia supplemented by blocking the brachial plexus. Postoperative radium treatment for twenty-four hours induced immediate necrosis, leaving two cavities which were long in healing, as was also a focus of congestion in the lung beneath.

Arterial Anesthesia.—Calcagno was compelled to amputate after the foot of the man of 43 had been injured in a railroad accident, the symptoms by the third day indicating severe infection and incipient gas gangrene. Both general and local conditions were alarming. He applied an Esmarch bandage at the middle and upper thirds of the thigh and then punctured the femoral artery through the skin and injected 0.25 gm. of procain with epinephrin, compressing the artery above at once. The anesthesia was complete in five minutes, and the temperature dropped the same day to normal. He reiterates in conclusion that the smooth and rapid recovery in this and his other cases refutes the objection that has been made to this arterial technic that it might favor the spread of the infectious process. It is merely a form of local anesthesia, and leaves vital organs unmolested.

Atresia of the Nasal Passages.—Jorge gives an illustrated description of the technic with which he corrected atresia following smallpox. The flaps for the purpose were taken from the cheek and there has been no retraction during the more than a year since. In another case he corrected the atresia by means of a flap from the arm.

Compound Fractures.—Rauenbusch gives twenty roentgenograms of different types of serious war fractures observed during his service in military hospitals in Germany during the war, and the treatment for each type.

Congenital Tumors of the Head.—In the first of the two cases illustrated by Goyanes, a large tumor at the vertex swung to and fro on a small pedicle. It had been noted from birth, and the child was a little over a year old when the meningocele was successfully removed. The second patient, a robust young man, had a congenital tumor corresponding to the superior longitudinal sinus of the dura. It fluctuated in size and was about as large as an egg when removed. On compression the tumor flattened out, confirming its hematocele nature. The profuse hemorrhage was arrested by tamponing which had to be kept up for eight days, the skin sutured over the gauze.

*Pathologic Physiology of Innervation of Stomach. P. Klee.—p. 275.
*Roentgenographic Examination of the Liver. E. Rautenberg.—p. 296.

Electrocardiogram of the Auricle.—Ganter found that the electrocardiogram of the auricle behaved differently from the electrocardiogram of the ventricle under the application of heat and cooling. He accepts this as evidence that the electrocardiogram from these two regions differs in its nature. The findings throw light further on the conduction of the impulse, as he explains.

Volume of the Pulse.—Reinhart was unable to find any characteristic feature in the systolic increase in the volume of the pulse peculiar to certain types of valvular disease. With failing compensation, the improvement under the influence of certain drugs is plainly evident.

War Nephritis.—Among the practical conclusions from Toenniessen's study of 254 cases of war nephritis (mortality, 3 per cent.) is that the diuretics to be selected should be those which act on the elements in the kidneys which are least damaged by the disease. This can be determined by the water and concentration tests and by estimation of the residual nitrogen, the amount of urine, the specific gravity and the behavior of the blood pressure. He warns that theobromin-sodium salicylate sometimes materially exaggerated the albuminuria in his total of 296 nephritis cases.

Agglutination Test After Vaccination Against Typhoid.—Brösamlen reports a positive response to the Gruber-Widal agglutination test in 74 per cent. of 482 healthy persons who had been vaccinated against typhoid. The reaction was still positive in 100 per cent. in a week or two after the vaccination, in 50 per cent. by the end of a year, and in 41 per cent. by the end of the second year. When any of the vaccinated developed typhoid, the titer ran up rapidly in 53 per cent., so that a rapid rise is corroboratory evidence of the typhoid nature of a febrile disease when at least three months have passed since the vaccination.

Improved Amhard Index of Kidney Functioning.—Peters describes a method with which it is possible to estimate approximately the weight of the kidneys in the living subject. The figure thus obtained he incorporates in the Amhard formula, and expatiates on the greater precision thus realizable, especially in children, instead of applying the Amhard

formula to them as if their kidneys were as large as those of adults. In one case, for example, the Ambard formula after nephrectomy was 0.121, which represents a loss of 66.5 per cent. Including the weight of the remaining kidney, showed a loss of only 48 per cent. The remaining kidney had hypertrophied and was compensating its lost mate to a most satisfactory extent.

Innervation of the Stomach.—In this second communication, Klee reports research on decerebrated cats, severing the splanchnic or other nerves to study the pathologic physiology of the gastric innervation.

Injection of Air in Roentgen Study of the Liver.—Rautenberg gives some roentgenograms to confirm the much clearer pictures obtained in examining the liver when about 3 liters of air are allowed to enter the abdominal cavity. One of his earliest communications on the subject was summarized in *THE JOURNAL*, July 11, 1914, p. 204, but, as a late editorial remarks (April 10, 1920, p. 1029), the importance of this advance in roentgenographic technic was not recognized until comparatively recently.

Syphilis of the Heart.—This may be diagnosed, says Luce, if, all other etiologic factors having been excluded, heart symptoms suddenly or gradually appear without any apparent clinical cause, especially in young subjects with a positive blood Wassermann reaction. The localization of syphilis in the septum may sometimes be established clinically by the appearance of symptoms of valvular rupture, spontaneous or following trauma, when a gummatous nodule in the region of the septum has broken through and opened communication between the right and left heart. Under such conditions clinical physical findings will be the same as characterize other defects of the interventricular wall especially the intensity of the heart sounds and the presence of a marked thrill over the whole heart area. The prognosis for life following specific treatment of syphilis of the heart is uncertain on account of the frequency of obliterative endarteritis occurring in the centers of irritation located in the heart.

Roentgen Therapy in Polycythemia.—In polycythemia Böttner strongly recommends roentgen therapy with strict control of the blood picture, especially of the leukocyte findings. Both the short and the long bones should be rayed. As to what extent, will depend on the severity of the illness. The long bones should receive the most attention, especially those that are paining. Only irritant doses should be applied to the spleen. Raying of the spleen alone is almost useless. Raying of the pelvic bones is contraindicated on account of possible injury to the genital glands. In leukemia, an intense raying of the spleen should precede raying of the osseous system.

Deficiency Bone Disease.—Hamel summarizes five cases representing all stages of osteopathies in adolescents due to the restricted war diet. At the general hospital in Hamburg, a highly nutritious diet, combined with cod liver oil and almost complete rest of body, together with intense active hyperemia and massage locally, brought good results. At first passive hyperemia (induced congestion) had been tried in various cases four, six and ten weeks, respectively, without improvement, but the effect of active hyperemia brought about by hot air baths, partial light baths, thermopenetration, energetic massage and light active and passive gymnastic exercise was marked. In fourteen days the patients were symptom-free

and in three weeks they were cured, as was shown by roentgenographic examination.

Clinical and Roentgenologic Aspects of Stenosis of the Small Intestine.—Kretschmer states that this stenosis may present no characteristic subjective symptoms. The more or less pronounced attacks of pain are the only constant feature. The well known clinical signs of intestinal stenosis are not regularly observable. Perhaps the most regular symptom is a form of meteorism—either tympanitic or assuming the aspect of intestinal rigidity, general or local. If the clinical symptoms are insufficient for a diagnosis, the roentgen picture will decide. There is often excessive peristalsis in the stomach.

Testicle Organotherapy in Hypertrophy and Atrophy of the Prostate.—Rohleder emphasizes that not hypertrophy but atrophy of the prostate is characteristic of old age. The symptoms of atrophy of the prostate are much the same as those of hypertrophy of the prostate: residual urine, dilatation of the bladder, difficult micturition, in the first stage. Chronic (partial or total) retention of urine with constant residual urine in the bladder, decrease in the curvature of the jet, desire to urinate immediately following evacuation of the bladder, mark the second stage. Incontinence, with the gradual development of insufficiency of the urinary organs, necessity of catheterization, painful micturition and possibly cystitis are the symptoms of the third stage. Rohleder gives an account of his results from testicle organotherapy, which were favorable in the first stage, palliative in the second and noneffective in the third stage.

Disturbance of Bladder Function with Myelodysplasia.—Sieben states that in the treatment of refractory cases of enuresis nocturna one should look for abnormalities or fissures in the sacral region. Of special importance is the presence of a circular indentation in the vicinity of the upper sacral vertebrae, which on palpation feels like a fistulous tract and is to be regarded as a rudimentary fissure. With purely functional enuresis nocturna, there are no signs of bladder disturbance during the day time, that is, so long as the patient is awake; but in the presence of myelodysplasia, bladder automatism and possibly hypofunctioning of the sphincter internus are constant, which often give rise to involuntary evacuation of the bladder during the day time.

Autogenous Vaccine Treatment of Glanders in Man.—Fischer reports a case of glanders that during a period of three years had been falsely diagnosed, first as tertiary syphilis and later as carcinoma or lupus. Until vaccine treatment was instituted the lesions showed no tendency to heal. Following vaccine treatment, as soon as a certain degree of immunity could be established, rapid and steady improvement began. At the beginning of the vaccine treatment it looked as if the patient would lose soon his whole nose, but after five injections the nose, which had partly necrosed, began to heal and the healing process continued to keep pace with the further injections. Fischer regards this as strong evidence that the autogenous vaccine was responsible for the cure, and that a spontaneous cure would scarcely have been effected, although he admits that it might otherwise be urged that in a large proportion of cases of glanders (50 per cent. according to Kolle and Hetsch) a spontaneous cure can be attained.

*Differentiation of Nephrosis and Brain Tumor. E. Janzen.—p. 51.

Influenza and Predisposition in Children.—The term used by Jamin and Stettner is "preparedness for disease" rather than "predisposition," and they discuss in particular the age of the child as a factor in susceptibility to infections.

Moeller-Barlow Disease.—Frank gives an illustrated description of the technic used in obtaining material from infants for research on metabolism, and tabulates the find-

ings from two cases. They confirm the retention of ash substances in the early stage of the disease and the abnormally high elimination of calcium during convalescence.

Action of Magnesium Sulphate on Calcium and Magnesium Metabolism in Infants.—Schiff injected the magnesium sulphate subcutaneously in three infants, and found that the output of calcium in the urine was much increased thereafter. Most of the magnesium salt was retained for several days.

Kidney Disease and Brain Tumor.—The coincidence of the nephrosis and the brain tumor in the boy of 6 was not suspected until death over two years after the first symptoms. The symptoms from the kidneys had masked those from the brain tumor or had been accepted as of uremic origin.

Roentgen Shadow of Entire Bronchial Tree in Man.

Rösler reports with roentgenogram the case of a man of 50 with carcinoma of the esophagus. The lumen was nearly completely closed, and in straining to swallow the suspension of barium for roentgenoscopy, it went astray into the air passages, and suddenly the entire bronchial tree cast a distinct and perfect shadow, the thin barium paste having rapidly spread throughout the whole. The man soon succeeded in coughing or hawking up the barium paste, stooping over, and did not seem to be any the worse for this mishap; there was no dyspnea and no cyanosis, and merely slight inconvenience. The cancer was removed sixteen days later but the patient did not long survive. The complicating paralysis of the vocal cords was evidently responsible for this alarming experience. In another case the opaque suspension found its way into part of the bronchi through a communication in the cancerous region. The cases warn against straining to swallow with cancer in the upper esophagus.

The Fundamental Conception of Cause. B. Fischer.—p. 74.

The Serologic Test for Syphilis by the Precipitin Method and the Use of Cholesterinized Organ Extracts.—Sachs and Georgi admit that in the application of their method there are some positive results that are not specific. They do not deny that this fact militates against the value of their test as a whole, and state that they have been endeavoring for some time to so modify the conditions of the test that unspecific reactions cannot occur. They find that the simplest way to avoid such reactions is to keep the test tubes the full time (eighteen to twenty-four hours) in the incubator instead of two hours in the incubator and the balance of the time at room temperature. However, this method is slightly less sensitive than the technic first recommended.

Chronic Myeloid Leukemia with Myeloid Skin Infiltration.—Saphier and Seyderhelm describe some peculiar skin phenomena appearing eleven days before death in a case of myeloid leukemia. Fairly hard, reddish nodules about as large as a pea developed on nose, jaw and brow and a small tumor on the cheek. The latter was movable on its base and was found to be suppurating in the depths. The efflorescence finally extended and presented the appearance of a flat infiltrate, the face cyanotic.

*Splenectomy in Pernicious Anemia. G. Spandler.—p. 86.

Neo-Arsphenamin in Syphilis of the Heart and the Aorta.

—Müller-Deham gives several detailed case reports and emphasizes the need of beginning neo-arsphenamin therapy with very small doses (0.05 or 0.075 gm.) and rejects as dangerous beginning doses of 0.3 gm. or more, as used by some. After seven years' experience treating syphilitics of this type he recommends that as soon as the general condition of the patient permits, in all cases of syphilitic aortitis, neo-arsphenamin treatment should be begun. The general condition of the patient and the Wassermann reaction will decide whether the treatment should be repeated. He recommends along with neo-arsphenamin the usual mercury and iodine therapy.

Meningitis Following Bacillary Dysentery.—Herschmann reports a case of meningitis following bacillary dysentery in a woman of 27, in which intravenous injections of polyvalent staphylococcus vaccines (Wagner-Jauregg) were successfully employed, a therapy that had repeatedly given good results in cases of acute, purulent meningitis. Toch recently reported a case of otogenous meningitis in which this therapy effected a complete cure. Herschmann thinks that these favorable results in etiologically different types of meningitis confirm the view of Wagner-Jauregg that in staphylococcus vaccine therapy we are dealing with the formation of nonspecific antibodies. He believes that when we consider how powerless we are in the face of meningitis if compelled to rely on the usual remedies, a wide field is here opened to vaccine therapy, especially since no untoward effects from this treatment have been observed.

Splenectomy in Pernicious Anemia.—Spengler gives an account of a case of pernicious anemia in which the red cell count became permanently normal following splenectomy. Before the operation the red cell count had been 1,140,000.

Reliable Sign of Viability of the Colon.—Hedri states that during operations in which it is necessary to ligate the mesentery or the mesocolon, the condition of the blood supply of the corresponding intestine can be learned by examination of the appendices epiploicae. If the stretch of intestine is suspected of not being adequately nourished, he cuts off one of these pouches of fat. If the artery in its stump bleeds, the suspected portion of the intestine may be regarded as adequately nourished and can be left without danger. If the artery in the stump does not bleed, the corresponding stretch of intestine cannot be safely left, and the resection must be more extensive.

*Constitutional Diseases in the Tropics. C. D. de Langen.—p. 1638.

Contraction of Muscle from Corneal Reflex. Anna Schoondermark.—p. 1642.

Medical Examinations.—Van Rijnberk remarks that the medical examination usually pays no attention whatever to the three things which yet are of the greatest importance as demonstrating fitness for the practice of medicine, namely, physical cleanliness, moral character and common sense. Some day some young professor on the examining board is going to surprise his colleagues by declaring that a certain candidate must be turned down "because no one with such dirty hands and black fingernails should be allowed to practice medicine." Dirty fingernails can do much harm in the sickroom, but no examining board now rejects a candidate on this account or for known pilfering tendencies.

Cause of Pseudohermaphroditism.—Van den Broek explains that the embryo stands under the influence of the mother's blood during its development in the uterus. It is thus all the time under the influence of the hormone from the mother's sexual glands. A male embryo develops its male sexual organs but, under the influence of the maternal ovarian hormone, female characteristics develop at the same time; the mammary glands are as well developed in newly born male infants as in female infants. After birth the maternal influence ceases. If the maternal hormone is secreted in excess it may outbalance the effect of the embryo's own male organs, and spurious hermaphroditism may result. This explains why male spurious pseudohermaphroditism is so much more common than the female.

Fracture of the Neck of the Femur.—Wassink gives illustrations of his method of immobilizing the fractured neck of the femur with a frame which holds two metal skewers driven parallel into the head and the great trochanter of the femur. A metal tube is mounted lower down on the frame, at right angles to the skewers, and this tube is held against the femur in a prolongation of the axis of the neck. Through this tube a drill is worked up into the neck. The frame ensures stability and exact localization of the parts, and healing occurs without chance for deformity, even without a plaster cast.

Constitutional Diseases in the Tropics.—De Langen writes from Java to confirm his previous statements in regard to the predominance of the sympathetic nervous system in the tropics. This modifies the chemical processes and the composition of the blood, and may explain the rarity of gastric ulcer and of some pathologic conditions common in Europe, and the extraordinary preponderance of others. Among the 422,943 patients in the hospitals of the interior of Java during the last ten years, no case of myxedema was encountered; only 6 of hypertrophied prostate; 30 of gallstones; 31 of leukemia; 10 of exophthalmic goiter, and 39 of diabetes, but there were 139 cases of appendicitis and 460 of cancer. Comparing these figures with similar material in Europe, shows the striking difference in the proportionate numbers of different diseases. He queries whether the tropical sympathicotony may not be responsible for this.

Mededeelingen v. d. Burg. Geneesk. Dienst, Java

1919, No. 8. Dutch-English Edition

*Immunity of Common Fowls to Plague. P. C. Flu.—p. 1.

*Experiments on Immunization against Plague. P. C. Flu.—p. 18.

*The Nitric Acid Test for Indol. J. Groenewege.—p. 61.

Immunity of Common Fowls to Plague.—Flu found that hens and roosters inoculated by intramuscular injection of plague bacilli, bore them without harm, and also even direct injection into a vein of half an agar culture of plague bacilli. Guinea-pigs injected with blood from the fowls, taken during the four following days, all died, showing that the bacilli had retained their virulence. None could be found in the fowl blood by the fifth or sixth day. The plague bacilli are engulfed by the phagocytes but retain their virulence to the last moment until they are seized by the phagocytes. As the most favorable temperature for development of plague bacilli is about 25 to 32 C, the naturally high temperature of fowls, 42 C., may have a bearing on their lack of susceptibility to the infection.

Immunization Against Plague.—Flu remarks that if the garrison at Malang had been vaccinated against plague, the fact that only one case of plague occurred in the garrison during the four years when thousands of civilians were dying of plague in the town, would undoubtedly have been ascribed to the protection from vaccination. But as it happened no vaccinations had been done in the garrison; rat-proof buildings were evidently responsible for the immunity of the soldiers. He warns that not unless conditions are exactly the same in the group of the vaccinated and the group of the unvaccinated are conclusions as to the efficacy of any vaccination justified. Inoculation of animals is more instructive, and Flu has been conducting extensive experiments in this line since the untimely death of his co-worker, Borger, who succumbed to laboratory plague infection not long ago. Flu used distilled water extracts from plague bacilli, inoculating guinea-pigs, monkeys and rats, and reports that the results with this compare favorably with those from the best of other methods, but even at the best we cannot hope to immunize up to 90 per cent. against the disease, as even the natural infection does not confer immunity to this degree.

The Nitric Test for Indol.—Groenewege presents evidence that all bacteria that form indol and do not reduce nitrate further than to nitrite, induce a positive response to the Salkowski test. To avoid error he has modified the technique somewhat, as he describes.

Ugeskrift for Læger, Copenhagen

March 18, 1920, 82, No. 12

*Deforming Osteochondritis of the Spine. H. Scheuermann.—p. 385.

*Tuberculosis and the First Born. S. Hansen.—p. 393.

Kyphosis in the Young.—Scheuermann has been studying 105 cases of what he calls kyphosis dorsalis juvenilis, with or without lateral curvature. It forms a group in which the curvature in the dorsal region cannot be corrected by an effort. Fully 88 per cent. of those affected were boys, and the ages ranged from 10 to 17, with three of 18 and 19. In all the cases there was a history of hard work, either on a farm or in a smithy or the like, or factory or bicycle messenger work, or in athletics. He reproduces the roentgen findings, and concludes from his analysis of conditions that the trouble is a process in the spine analogous to that of the Calvé-Perthes deforming osteochondritis of the hip joint. Instead of the usual name for it, "muscular kyphosis" or "apprentices' kyphosis," it should be called juvenile deforming osteochondritis of the spine.

Tuberculosis and the First Born.—Hansen refers to Karl Pearson's works on the handicapping of the first born, and relates that at two sanatoriums in Denmark there was a much larger proportion of the first born among the total 5,635 inmates than would seem to be probable unless the number of births does have some influence on the resisting powers. Investigation of large series of schoolchildren, however, failed to confirm that positive reactions to the skin tuberculin test were proportionately more frequent among the first born than among others, and no physical differences could be detected between them. He accepts the possibility, however, of endogenous factors determining the flaring up later of latent tuberculosis. One such factor may be a congenital inferiority of the lung tissue, restricted to the first born, and traceable to undernourishment. It is possible also that this inferiority may be heritable.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1920

The following journals have been abstracted in the Current Literature Department of THE JOURNAL during the past six months. Any of the foreign journals will be lent by THE JOURNAL to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days. Only one journal may be borrowed at a time. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Domestic journals can be obtained by sending the approximate amount direct to the respective publishers. Thus most of the journals indexed are accessible to the general practitioner, no matter where he may be located.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "T," Therapeutics; "MI," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an "Original Article" in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "B," "D" and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author follows the subject entry in brackets.

For author index see page 1840.

ANALGESIA: See Anesthesia
ANAPHYLAXIS: See also Immunity
ANAPHYLAXIS, [Louste] 1546
anaphylactoid phenomena from intravenous administration of colloids, arsenicals and other agents, [Hanzlik & Karsner] 828
and antipyrin, 538
and asthma, [Pagniez] 920
as factor in epilepsy, [Pagniez & Lieutaud] 65
cutaneous hypersensitiveness, [Fleischner & others] 55
from insufficiency of pancreas, [Nathan] 831
ANASARCA, puncture in treatment of, [von den Veldeu] 774
ANATOMY, relation of, to present day surgery [Mayo] *367
teaching of, [Jackson & others] 823—ab
ANEMIA, atypical, chronic, [Herzog] 1549
catalase content of blood in different types of, [Krumhaar & Musser] 1738—ab
hemolytic, importance of changes in plasma in, 893—E
hemolytic, partial splenectomy in, [Speldel & others] 1604
in young children, [Lenoble] 1194
pernicious, [Marcora] 496
pernicious, at an advanced age, [Ward] 918
pernicious, bile pigments in, [Schneider] *1759
pernicious, chemical difference between young erythrocytes from blood of, and normal persons, [Locke & Hackman] 1738—ab
pernicious, hypertrophy of pylorus with, [Kleemann] 1358
pernicious, of unknown origin, therapy of, [Zadek] 431
pernicious, report of case of combined sclerosis due to, [Redwood] *1825
pernicious, splenectomy in, [Spandler] 1805
pernicious, transfusion of blood in, [Anders] 56, [Scheel & Bang] 1294
pernicious, treatment of, [Hamman] 283
serotherapy in, [Prado Pastana] 496
splenic, in children, [Amesse] 418, [Aschenheim] 1492
splenic, revision of Banti's disease, [Mitamura] 1135
splenic, splenectomy in, [Ceballos] 430
ANESTHESIA, accidents during, [Waters] 1539—ab5
apparatus for use of ethyl chlorid with other agents, [Erdmann] *1518
arterial, [Calcagno] 1803
- ANESTHESIA**, blocking of pneumogastrics, experimental, [Ozorio de Almeida] 1058
blocking splanchnic nerves, [Hoffmann] 991, [Kappis] 1059
cocain, for nasal surgery, [Andrews] 419
discoverer of, [Lewis] 1184—C
general, present status of, from hospital viewpoint, [Ehrlich] 1484
general, mixture of ethyl chlorid, chloroform and ether for, experience in war surgery, [Quain] 129—ab
in experimental surgery, [Mann] 1540—ab
induction of analgesia and, by oral administration of various drugs, [Ficklen] 282, 1540—ab
intrasplinal, [Delmas] 137, [Trogu] 1290
intrasplinal, toxic meningitis after, [Bracht] 144
local, benzylcarbinol in, [Hjort & Eagan] 281
local, in abdominal surgery, [Grove] 1481—ab
local, in neuro-surgery, with special reference to evulsion of sensory root of gasserian ganglion, [Downan] *382
nerve blocking for nasal surgery, [Reaves] *1514
nitrous oxid-oxygen, advances in, [McKesson] 1540—ab
nitrous oxid-oxygen in labor, advantages of, [Turner] 352
nitrous oxid-oxygen, literature on, 195
nitrous oxid-oxygen, open method of, [Gwathmey] 1540—ab
nitrous oxid-oxygen, relaxants in, [Calne] 1540—ab
rectal, changes in rectal mucosa following intrarectal ether narcosis, [Savignac & Vidal] 1354
research organization, 333
research, prize for, 898
sacral, fatalities after, [Zweifel] 1138
sacral, high, [Schuster] 1493
segmental hyperalgesia in visceral lesions, [Jones] 1709
spinal, [Cooke] 1480—ab
spinal, by-effects with, [Hosemann] 991
spinal, death following, [Ireland] *19
therapeutic use of carbon dioxide after, [Henderson & others] *783
ANESTHESIN-ABBOTT, 1577
ANESTHESIN-CALCO, 675
ANESTHETICS, data on, 685
experimental studies on effects of, in shock, [Cattell] 1540—ab
local, comparative toxicity of, and of antipyretics for earthworms, [Sollmann] 700
local, do they precipitate proteins? [Sollmann] 205
some anesthetic relations, [Miller] 1539—ab
ANEURYSM, aortic, blood pressure in, [Crance] 980
aortic, medical treatment of, [Mac-lachlan] 1670
aortic, rupture of, [Herrick] 202
arteriovenous, [Verth] 1492
arteriovenous, treatment of, by intrasacral method of suture (endo aneurysmorrhaphy), [Matias] 1601
in liver, [Käding] 925
multiple, [Anderson] 284
of left ventricle, [Lutembacher] 1677
of right vertebral artery, [Howe] 557
traumatic, [Flannery] 829, [Valentine] 1279—ab
traumatic, and wounds of vessels in general, [Dobrovolskaia] 920
wiring of, [Tagliavacche] 770
with acute aortitis, [Merke] 1131
ANGINA, cardiac, in child of 6 years, [Rutherford] 1675
erosive, [Harvier & de Léobardy] 768
pectoris, [Martinet] 1489, [Gallavardin] 1608

reactions, [Moore & Foley] 280, [Martin] *1218
silver salvarsan, [Rille & Frühwald] 568, [Boas & Kissmeyer] 1060, [Nageli] 1289
tubing as cause of reaction to intravenous injection, especially of arsphenamin, [Stokes & Busman] *1013, [Goldenberg] 1271—C
- ARTEFACT** "spirochetes," 1783—E
- ARTERIOSCLEROSIS** and high protein diets in rabbits, [Newburgh] 1682
and blood pressure, [Harpuder] 1682
and hypertension, [Moschowitz] 56
trauma in relation to, [Fraenkel] 837
- ARTERY**, abnormalities of vertebral artery, [Canizaros] 1486
carotid, spontaneous dilatation of, [Deus] 431
cartoid, ligation of, for traumatic exophthalmos, [de Lapersonne] 493
internal iliac, ligation of, in gynecologic operations, [Massart] 557
middle meningeal, injury of, [Salomon] 498
occlusion of right posterior inferior cerebellar, [Hall] *1157
peripheral, pathology of, [Weisel & Lowy] 1360
pulmonary, congenital heart lesion with unusual origin of, [Plowden] 284
roentgen-ray study of great vessels, [Martin] *723
spasm of walls of, [Morelli] 1490
study of arteries supplying stomach and duodenum and their relation to ulcer, [Reeves] 1284
- ARTHRITIS**: See also Gout; Rheumatism
- ARTHRITIS**, active movements in treatment of, [Usland] 1352
acute cervical, following scarlet fever, [Mayet & Laval] 1355
aseptic purulent, [Apert & Cam-
bassédès] 138
basal metabolism in, [Pemberton & Tompkins] 1191
deformans, etiology of, in children, [Byfield] 555
deformans, loose bodies in, [Hahn] 838
etiology of, 407
focal infection and arthritis, [Gib-
ney] 828
foreign body, [Hirsch] 991
gonococcus, [Lorenzo] 1748
gonococcus, differentiation of, [Du-
four] 63
gonorrheal, [Klose] 637
gouty, treatment of, [Petersen] 1138
in army, [Pemberton & Robertson] 1191
in army based on 400 cases, relation of creatinin metabolism to arthritis, [Pemberton] 1542
in army based on 400 cases, roentgen-ray evidences, clinical considerations, treatment, summary, conclusions and clinical abstracts of cases studied, [Pemberton] 1542
meningococcus, [Nobecourt & Paraf] 1745
streptococcus viridans infections of mouth and throat with reference to neuritis and, [Hay] 1072
studies on nitrogen, urea, etc., in, [Pemberton & Foster] 1191
- ARTHRITIS** of shoulder, [Serafini] 1289
- ASCARIASIS**, diagnosis of, [Martinez] 1802
some features of, 108—E
- ASCARIS** as cause of pulmonary disease, [Steiner] 1801
lumbrocoides in fallopian tube, [Nacken] 1749
- ASCITES**, chylous, due to carcinoma of stomach, [Hendricks] *869
with inherited syphilis, [Bonorino & Carulla] 835
- ASPHYXIA**, fetal, [Kirkham] 418
of the newly born, [Mink] 570
sinus arrhythmia from, [Gallavardin] 1677
- ASPIDOSPERMA**, therapeutics of, [Wilcox] 134
- ASPIRATION** during operations, [Rocher] 563
- ASPIRIN**: See also Acid, Acetylsalicylic
- ASPIRIN** Bayer and acetylsalicylic acid, 1664
- ASSOCIATION** for research in nervous and mental diseases, 1528
of American Medical College elects officers, 683
of American Physicians, election of, 1528
of Surgeons of Great Britain and Ireland, 471
of Medical Museums, 1466
of Surgeons of Great Britain and Ireland, 538, 1179
- ASTHENIA**, Neurocirculatory: See Heart, Irritable
- ASTHMA** and anaphylaxis, [Pag-
alez] 920
and pregnancy, [Ruibal Salaberry] 142
bronchial, treatment of, [Gottlieb] *931
bronchial, vaccine treatment of, [Hutcheson & Budd] 1128
epinephrin in, [Maira] 139, [Hoxle & Morris] 1602
factors concerned in asthma and their treatment, [Jones] 1053
in child, [de Villers] 141
peptone treatment of, [Auld] 1604
protein sensitization in hay fever and, [Sanford] 1424
relation of sputum bacteria to, [Rackemano & Koessler] 167-ab
- ASYSTOLIA**, renal syndrome with, [Josue & Parturier] 1426
- ATAXIA**, Locomotor: See Tabes Dorsalis
remittent, of ascending aorta, [Cantelli] 986
- ATECHNIA**, [Laignel-Lavastine] 1288
- ATHLETES**, treatment of injuries to, [Stewart] *947
- ATHREPTIC** infants, experimental work with sodium cacodylate on, [Clarke & Dow] 1420
infants, feeding of, [Lonsway] 1280—ab
- ATLAS**, congenital luxation of, [De-
mole] 290
fracture of, [Jefferson] 1194
- ATROPHY** of muscle from concus-
sion, [Leri & others] 833
progressive, muscular, [Del Valle] 141
progressive, muscular, in children, [Fiore & Guidi] 1133
spinal muscular, probably of Werd-
nig-Hoffman type, [Knox & Powers] 701
treatment of, in denervated muscles, 1260—E
- ATROPIN**, diagnostic significance of pupil reaction to, [Siciliano] 426
effect of, on chloroform hyper-
glycemia, [Ross] 1674
perfusion of medulla of turtle by, [Bush] 700
- AURAE**, nature of, [Alford] 555
- AUSTRALASIAN** Medical Congress, 43, 747, 1467
- AUSTRALIAN** Commonwealth public health service, 1033
- AUSTRIA**, physicians' children in, 1467
- "AUTO-HEMIC SERUM"** cure for laziness, ugliness, frigidity and many other things, 477—P
- AUTOINTOXICATION**, [Goodman] 1482—ab
- AUTOMOBILE** accidents, 1721—ab
deadly motor car, 1461—E
privileges accorded physicians driv-
ing, 1185
using emblem on, 1654
- AUTOPSY**: See Necropsies
- AUTOSEROTHERAPY**: See Sero-
therapy
- AVIATION**, commercial, [López] 68
consulting medical committee of aviation service, 1532
medical examination of aeronauts, 1530
medical science and aeronautics, 617
physiologic significance of record flight, 805—E
psychology of, 1468
show, in Paris, physiology at, 471
- AVOCADO** fat, 893—E
- AXILLA**, deep phlegmon in, [Levy] 1059
papular itching eruption of, [With-
ers] 280
- AZOTEMIA** with pulsus alternans, [Esmein & Heitz] 1489
- AZUROPHILIA** in blood in measles, [Canelli] 1612—B
- B**
- BABINSKI** phenomenon, significance of, [Friedman] 979
reflex, suppression of, [Nolca & Radovici] 1356
- BACCELLI**, memorial tributes to, 745
- BACILLUS** aerogenes capsulatus infection, [Vogt] 1137
aerogenes capsulatus infection, severe case with recovery, [Adams] 1281
bronchiseptics as cause of infectious respiratory disease, [Hoskins & Stout] 915
Bulgareus, [Squibb] 1167
Carriers: See under names of diseases
colon and typhoid bacilli, utilization of capillary attraction to differentiate them, [Vogt] 1137
colon, in vagina as cause of leukor-
rhea and sterility, [Barbash] 981
colon-typhoid bacilli isolated from case of furunculosis, [Oliver & Schwab] 1543
colon-typhoid group, methods of isolation and identification of members of, [Bronfenbrenner & Schlesinger] 763
Hoffmann, and diphtheria in India, [Knowles] 423
Influenza: See Influenza Bacilli
malle, studies on, [Koga & Otsu-
ho] 1744
of Morgan No. 1: a metacolon bacillus, [Thijotta] 763
Pfeiffer: See Influenza Bacilli
Tuberculosis: See Tuberculosis Bacillus
Typhoid: See Typhoid Bacillus
- BACK** injuries, treatment of, [Mar-
shall] 626
- BACKWARDNESS**: See Feeble-
mindedness
- BACTERIA**, culture medium for maintenance of stock culture of, [Worth] 556
encountered in heat sterilization of surgical ligatures and sutures, [Fenger & others] *24
fate of bacteria introduced into upper air passages, [Bloomfield & Iluck] 1601, [Bloomfield] 628

- BACTERIA** in upper respiratory passages, safeguard against, 252—
infection route in respiratory tract, [Winternitz & others] 1421
invasion through upper air passages, 1522—
life, death and bacteria, 394—
oral sepsis and elective localization of, 677—
standardization of bacterial suspensions, [Gates] 204
yield of bacterial substance for area growth, [Harvey] 631
- BACTERIOSTASIS**, selective, in treatment of infections with gentian violet, [Churchman] *145
- BACTERIURIA**, vacchotherapy of, [Nolff] 207
- BACDAD BOILS**, transmitting agent of, [Acton] 830
- BAKER**, bacillary dysentery spread by, [Louste & Godlewski] 919
- BAKING**, Research Institute of, 1335
- BALDNESS**, autoplasmic surgical treatment of, [Passot] 1679
- BALKAN** frames of iron pipe, simple clamp for making, [Johnson] *1230
- BANANA**, antiscorbutic value of, [Lewis] 58
nutritive value of, [Sugiura & Benedict] 133
- BANDL'S** ring impedes delivery, [Brandt] 1294
- BANT'S DISEASE**: See Anemia, Splenic
- BARBITAL** addiction, 544
[Chris] 951
Elixir Barbitol Sodium—Abbott, 1231
poisoning, [Taub] *459, [Moszelk] 1613
Sodium-Chris, 951
- BARLEY**, nutritive value of proteins of, [Osborne & Mendel] 1049
- BASEDOW'S DISEASE**: See Goiter, Exophthalmic
- BATHS**, thermal, with cardiovascular disease, [Grunow] 773
- BEANS** and growth, 1170—
poisoning from, 812
- BED-SORES**, pathogenesis and treatment of, [Wieting] 989
- BEE** poison, 1458—
E
- BELGIAN** physicians' and pharmacists' relief fund, close of, 262
Society of Psychiatry, 1656
Surgical Congress, 188
- BELGIUM**, child welfare work in, 1176
letter, 1110, 1267
medical press of, 1110
- BENCE-JONES** protein, characteristics of, 1580—
E
- BENEDICT'S** basal metabolism determination, 1273
- BENZENE**: See Benzol
- BENZIDIN-POLYCHROME** stain for blood, [McJunkin] *17
- BENZOL** in leukemia, [Pignetto] 430
poisoning, chronic, [White] 979
- BENZYL**, 1343
alcohol, antihelmintic action of benzol esters and, [Macht] 700
- BENZYL-CARBINOL**, a local anesthetic, [Hjort & Eagan] 281
- BERBERI** among Chinese in France, [Leggate] 491
analysis of early cases of, [Hepburn] 1487
anti-berberi vitamin content and antiscorbutic property of sundried vegetables, [Shorten & Roy] 1424
mucor isolated from feces in, [Kiyosaki] 561
Takaki's work in, 1404—
E
- BETANAPHTHOL**, poisoning in treatment of hookworm disease, [Smillie] *1503
- BIBLE**, leprosy in the, [Boinet] 704
- BILE** by rectum in treatment of constipation, [Bensaude & Vicente] 209
dissociated elimination of elements of, [Waldorp] 987
dissociated retention of elements of, [Bouchat & Lamy] 832
ducts, anomalies in course of, [Alvarado] 363
duct, common, sphincter at duodenal end of, [Mann] 59
duct, common, sphincter of, 1648—
E
ducts, drainage of, [Ribas y Ribas] 140
pigments in pernicious anemia, study of, [Schneider] *1759
pigment in serum, clinical significance of, [Menlengracht] 68
tract, reconstruction of, [Nicholson] 67, [Collins] 422
- BILHARZIASIS**, treatment of, with tartar emetic in South Africa, [Cawston] 1545
- BILIRUBIN** in blood, [Bauer & Spiegel] 1682
- BIOLOGIC** preparations, official methods of control of, [McCoy] *1553
therapeutics, commercial domination of, 466—
E, [Bass] 619—
C
- BIRTH** rate, 1469
rate and sex education, 1338
rate, (class fertility), 1530
rate, decrease in, [Hunziker] 143, 1414
rate, increasing, 1339
rate, measures to promote increase in, in France, 747, 900
- BISMUTH** and kaolin in treatment of stomach disturbances, [Hayen] 1678
poisoning, [Constantinescu & Joneanu] 1490
subnitrate, substitute for, 1531
substitute for, [Hayen] 1678
- BLACKWATER FEVER**, [Houssiau] 64
pathogenesis of, [Zlocisti] 1199
- BLADDER** calculi, migrating, [Barringer] 979
calculi, recurrent, associated with calculus in diverticulum and contracture of vesical orifice, [Davis] 1798
calculi, unusual urinary calculi, [Harris] *1388
complete closure of, after coagulation of tumors, [Kölischer & Eisenstaedt] *801
diverticulum, etiology and treatment of, [Minman] 489
gangrene of, following vaginal carcinoma operation, [Husen] 773
hour-glass, [Caulk] 203
in secondary syphilis, [Zimmermann & Levy] 629
inflammation of trigon of, chronic, in female, [Lindeman] 421
instrument for illumination and suction in certain suprapubic operations, [Watson] *389
rupture of, [Celestia & Buzzi] 987, [Gordon] 1285
tumors, diagnosis and treatment of, [Herbst & Thompson] *91
- BLANCO**, José Luis, bogus diploma held by, 1336
- BLASTOMYCOSIS**, blastomycetic dermatitis with epileptic seizures, [Mendes] 288
involving prostate and seminal vesicles, [Parmenter & Simpson] 979
tuberculin reaction in, [Lozado] 1134
- BLIND**, school for, in Mexico, 1337
welfare of, 956—
ab
- BLINDNESS** due to methyl alcohol, lumbar puncture in, [Zethelius] 1138
methyl alcohol poisoning and, [Harboe] 1532
- BLOOD**, acid reaction of, and albumin requirement, [Fuhrge] 213
amount of blood expelled at each heart beat, [Piesch] 1429
antitrypsin in, [Tachigara] 1428
azurophilia in, measles, [Csnelli] 1612
bilirubin in, [Bauer & Spiegel] 1682
carbon monoxid in, determination of, [Van Slyke & Salvesen] 58
catalase in, in different types of anemia, [Krumbhaar & Musser] 1738—
ab
changes in, on a spleen tissue diet, [Brinckmann] 774
chemical analysis of, [Poyales] 363
chemical composition of, in cancer, [Theis & Stone] 280
chemical examination of urine and, in normal pregnancy and in toxemia of pregnancy, [Loose] 1421
chemistry, [Chapin & Myers] 55
chlorids in, [Rodillon] 985
chlorids in, determination of, [Austin & Slyke] 1049
circulation, action of gum acacia on, [Bayliss] 1423
circulation, development of collateral circulation, [Bolognesi] 564
circulation in lungs, pharmacology of, [Wolfer] 214
circulation of, low barometric pressure and changes in, 250—
E
circulatory disturbances of extremities, importance of early diagnosis in, [Bernheim] 1742
coagulation, action of snake venom on, [Houssay & Sordelli] 140
coagulation of, in serous cavities, 748
coagulation, influence of blood platelets on, [Emmel] 914
- BLOOD** coagulation time and the prognosis, [Corachan & Gallart] 68
coagulometer, new, [King & Murray] *1452
composition of, in arid climates, [Grober] 365, [Bickel] 990
corpuscles, diffraction phenomena in, 685
corpuscles, red, chemical difference between young erythrocytes from blood of pernicious anemia and normal persons, [Locke & Hackman] 1738—
ab
corpuscles, red, preservation of erythrocytes after death, [Strassmann] 637
corpuscles, red, resisting power of erythrocytes, [Bauer & Aschner] 1491
corpuscles, red, vital shape of, [Wyss] 1680
Corpuscles, White: See Leukocytes
effects produced on blood picture by oxygen inflation of peritoneal cavity, [Goodman] *1515
equilibrium between oxygen and carbonic acid in blood, [Henderson] 1049
for Wassermann tests, new method for procuring, [Owen & Martin] *98
freezing point of, is low in diabetes, [Lippmann] 926
gases, analysis of, [Straub & Meier] 1682
in influenza, changes in, [Kinsella & Brown] *1070
influence of splenic extract on number of corpuscles in circulating blood, [Downs & Eddy] 1281
low carbon dioxid combining power of, [Pepper & Jonas] 1794—
ab
meningococcal activity of blood, [Matsunami] 1483
methemoglobin in, method for determination of, [Stadler] 828
micro-analysis of, [Feigl] 926
nitrogen equilibrium of, of cancer patients, [Loeper & others] 1680
occult modification of benzidin test for, [Boas] 289
of insane persons, [Weston] 556
plasma chlorids versus renal function, [Rappleye] 418
plasma, constancy of volume of, in disease, [Bock & Minot] 1599—
ab
platelet count in diseases of, [Cram] 1191
platelet extract by mouth, [Jost] 365
platelets, [Marchesini] 1426
platelets, counting of, 1406—
E
pressure, action of volatile substances on, [Yamada] 1428
pressure and arteriosclerosis, [Harpunder] 1682
pressure and gallop sound, [Amblard] 1801
pressure, arterial circulation in infants, [Lesné & Binet] 918
pressure, arterial tension in disease, [Villaret & Dufour] 919
pressure, arterial tension in chronic pulmonary tuberculosis, [Marfan & Van Nieuwenhuysse] 1800
pressure, determination of, [Villaret & Dufour] 359
pressure, drop in, under arsenical treatment, [Tourelle] 211
pressure, effect of epinephrin on, [Bauer] 638
pressure, effect of strain on heart rate and, [Dawson & Hedges] 626
pressure, high, [Vaquez] 139, [Allen] *652
pressure, high, and arteriosclerosis, [Moschowitz] 56
pressure, high, associated with endocrine dyscrasia, [Engelbach] *1619
pressure, high, climacteric, [Hopkins] 207
pressure, high, endocrine therapy of, [Bandler] 1797
pressure, high, treatment of, [Moschowitz] 1670
pressure in operative surgery, [Miller] *514
pressure in psychoses, [Euzière & Margat] 139
pressure in typhoid, value of study of, [Andrews] 279—
ab
pressure, low, in typhoid, [Sanmartin] 835
pressure measurements, arm in, [Kahn] 202
pressure, postural changes in, [Seewall] 202
pressure, sphygmo-oscillographic cuff, [Mougeot] 285
- BLOOD** pressure, unilateral alterations in, [Cyriax] 492
regeneration, [Buell] 57
stain, benzidin-polychrome, for, [McJunkin] *17
sugar content of, and carbohydrates, [Sakaguchi] 637
sugar, effect of hemorrhage on alkaline reserve and, [Tatum] 488
sugar, estimation in diagnosis and treatment, [Cambridge] 918
sugar in depancreatized dogs, [Delatour] 1542
sugar, influence of muscular work on, [Brosamen & Sterkel] 1549
sugar, influence of ovaries on, [Baillod] 364
sugar, simplified and improved method for determination of, [Folin & Wu] 1049
transfusion apparatus, [Stanley] *671, [Greenhouse] 967—
C
transfusion before operation in severe secondary anemias, [Williamson] 1545
transfusion in obstetrics, [Loose] 1421
transfusion in malignant measles, [Terrien] 768
transfusion in pernicious anemia, [Anders] 56
transfusion of antibacterial blood; report of case, [Little] *734
urea content of blood in an epileptic, [Dufour & Semelaigne] 985
use of blood and blood serum in treatment of disease, [Johnson] 1483
vessels and pressure, [Hill] 917
vessels, capillary, recently discovered aspects of, 178—
E
vessels, effect of arteriovenous fistula on heart and, [Reid] 1048
vessels, regenerative processes in, [Bier] 497
vessels, roentgen-ray study of great vessels, [Martin] *723
vessels, traumatic aneurysms and wounds of vessels in general, [Dobrovolskaia] 920
viscosimetry of, [Josue] 1608
viscosity of, [Pinilla] 1058
volume, 395—
E
volume studies, blood volume as determined by change in refractivity of serum nonprotein fraction after injection of certain colloids into circulation, [McQuarrie & Davis] 1281
volume studies, repeated determination of blood volume at short intervals by dye method, [Smith] 1281
- BLUE**, General, goes abroad, 959
- BLUE DISEASE**: See Cyanosis
- BOARD**, apical medical, corresponding to patent office, [Sorelli] 701
- BOAT**, liability for typhoid contracted on, 1189—
MI
- BOECK'S** sarcoid, [Stumpke] 1493
- BOERICKE** & RUNYON tablets, 818—
P
- BONE**, buried, experimental study of, [Ely] 57
cavities, treatment of, [Martin] 203
cavities, wax and paraffin to fill in, [Wassertrüding] 1492
changes in feet following fracture of vertebra, [Bryan] 1483
condition analogous to rickets in child of 5 months, [Brade-Birks] 1353
decalcification of, [Tiller & Witas] 1678
deficiency disease of, [Hamel] 1804
disease from undernutrition, [Böhme] 497
general method of repairing loss of bony substance and of reconstructing bones by osteoperiosteal grafts from tibia, [Delaogeniere & Lewin] 1793
graft, autogenous, for repair of fractures of long bones, [Martin] 201—
ab
graft for correction of kyphosis, new method of inserting, [Grantham] 630
graft in treatment of active tuberculous process, [Robertson] 427
graft, treatment of fractures at U. S. Army General Hospital No. 3, Colonia, N. J., [Albee & Welgel] *589
hydatid disease of, [Corlette] 767
hydatid disease of, multilocular, [Corlette] 984
Paget's disease of, [De Massary & Lecheile] 1286

- BONE**, repair of, [Gallie & Robertson] 208, 604—E
sarcoma of, treatment of, [Coley] 57, [Calderon] 363
setter, proposed medical degree for, 1413
"setting": forced movement, [Mennell] 767
syphilitic lesions, multiple, [Gilbert & Saint-Girons] 704
transplantation, use of beef-bone screws in, [Henderson] *715
tuberculosis of, roentgen treatment of, [Espinola] 565, [Cottenot] 768
war pathologic conditions in, [Koeppen] 569
BOOK plates wanted, 1108, 1175
BORDET-WASSERMANN REACTION: See Wassermann Reaction
BOTULISM, [Bitter] 924
condition of olives responsible for New York outbreak of, [Sisco] 680—
destruction of bacillus botulinus toxin by boiling ripe olives, [Grünfeld] 691
different types of, 186
from canned ripe olives, 109—E, 127, 466—E, 530—E, 1261—E, [Thom] 1475—C
from eating ripe olives in Memphis, 470
ocular manifestations of, [de Saint-Martin] 985
outbreak of, [Jennings & others] *77, [Sisco] *516
preliminary report of study of antitoxin of bacillus botulinus, [Dickson & Howitt] *718
resistance of spores of *B. botulinus*, [Dickson & others] 130
summary of Bureau of Chemistry investigations of poisoning due to ripe olives, [DeBord & others] *1220
BOVINIA, 1661—P
BOWEL: See Intestine
BRACE for tuberculous spines, [Morrill] *949
BRACHIAL birth palsy; pseudo-paralysis of shoulder joint origin, [Thomas] 1541
plexus compression of lower trunk of, by first dorsal rib, [Stopford] 207
BRADYCARDIA, orthostatic, [Lutembacher] 285
BRAIN: See also Cerebellum; Cranium; Pituitary Body
BRAIN abscess following middle ear and mastoid infections, treatment of, [McCoy] 1050
abscesses, multiple, secondary to bronchiectasis and kyphoscoliosis, [Saelhof] 1673
actinomycosis of, [Sagredo] 361
and genetic function, [Desogus] 1611
birth injury of, [Beneke & Zausch] 926
cancer, necropsy findings in, [Nagayo] 1682
chemical differentiation of sections of, [Landau] 290
cyst, death after spinal puncture with, [Ponce de León] 835
cysticercosis of, [Santa Cecilia] 1290
deep localization in cerebral cortex, [Hook] 1673
dilatation of lateral ventricle in epilepsy, [Thom] 700
disease; deviation of head and eyes in, [Siciliano] 987
epidermoid papillary cystoma involving third ventricle, [MacPherson] 1350
extraction of bullet in lateral ventricle, [Regard] 495
glioma of, and encephalomyelitis, [Howe] 557
gunshot wounds of, with retained missiles, [Bagley] 199—ab
hemorrhage, prophylaxis of, [Paolletti] 1197
hydatid disease of, primary, [Fleming & Bury] 337
injuries, pathologic anatomy of traumatic fractures of cranial bones and concomitant brain injuries, [LeCount & Apfelbach] *501
intracranial pressure, simple method of measuring, [Caldwell & Kieley] *951
macrophages in brain repair, 1523—E
puncture of, [Pastsch] 143
repair in rat, study of, by use of trypan blue; vital staining of macrophages, [Blacklin] 1350
BRAIN, surgery, to wall off sub-arachnoid space in operating on brain, [Lemaître] 1680
tumor, differentiation of nephrosis and, [Janzen] 1804
tumors as seen in hospitals for insane, [Morse] 1350
tumors in children, [Rivarola] 1058
weight in congenital mental deficiency, [Limb] 561
BRAISTED, Admiral, honorary degrees to, 1586
BRAN, extract of, in infant feeding, [Fernandes] 1611
"BRAZIL-MEDICO," changes in, 746
BREACH of contract to furnish medical services, 2178—M
BREAD, nutritive efficiency of bread proteins, [Sherman] 488
BREAST, cancer of, [Conill] 140, [Neander] 570
cancer of, and postoperative raying, [Perthes] 925
cancer of, in male, [Calcagno] 1803
cancer, pathologic anatomic findings in prognosis of, [Iselin] 834
cancer, radiotherapy for, [Jolles] 1551
gumma of, report of probable case, [Thompson] *791
tumors, malignant and benign, [Davis] 130—ab

 chart for rapid calculation of calorific values of, [McClendon] *101
 effect of deficient dietaries, [McCarrison] 982
 one-sided, [Jacoby] 990
- DIGESTIVE TRACT**: See Gastrointestinal Tract
- DIGITALIS**, [Espina] 141
 administration of, [Pardee] 283
 administration of, by "Eggleston method," [Eggleston] *733
 certain differences in action of strophanthin and, [Cohn & Levy] 1592—ab
 cultivated, [Gaglio] 922
 effect of, on diuresis, [Jarisch] 1748
 effect of therapeutic doses of, on contraction of heart muscles, [Cohn & Levy] 1597—ab
 in pulmonary tuberculosis, [Burrand] 632
 therapeutic value of, 544, [Krehl] 1291
- DIONOL**—the glorified petrolatum, 410—P
- DIPHTHERIA**, adenoid, [Myers] 282
 among newly born, [Hollatz] 1201
 antitoxin treatment of, [Weill-Halle] 1055
 antitoxin vs. horse serum, 35—E
 bacilli, effect of brilliant green on, [Kolmer] 557
 bacilli, new stain for, [Albert] *28
 bacilli, virulence of, from diphtheria patients and from carriers, results of 548 tests, [Wadsworth] *1633
 bacillus, biologic studies of, [Havens] 1796
 carriers, 266—ab, [Huet] 1294
 carriers, treatment of, [Arloing & Stevenin] 494
 cats and, 892—E
- DIPHTHERIA**, control of, by cultures of noses and throats of school children, [Gloyne] *83
 heart in, [Aviragnet & Lutembacher] 1677
 immunity test (Schick Test), 1231
 in India and Hoffmann bacillus, [Knowles] 423
 mortality, [Dubourg & Guénard] 1130
 nasal, in new-born infants, [Becker] 569
 of nose and throat in young infant, [Spolverini] 426
 of umbilicus in new-born, [Hunkel] 1429
 paralysis following, [Spolverini] 1133
 paralysis following, meningeal reaction with, [DuCamp & Carleu] 985
 paralysis following, report of 2 cases, [Boorstein] *512
 polyneuritis of diphtheric origin without apparent diphtheria, [Ponce de Leon] 428
 positive throat in convalescents, [Brownelle] 1353
 prophylaxis of, 1587
 Schick reaction in, [Renault] 1286
 Schick reaction for determination of susceptibility to, [Leete] 561
 stenosis of trachea following, [Brady] 1750
 treatment, administrative meddling in medical affairs, 1469
 treatment of, [Albrecht] 990
 wound, [Kehl] 1137
- DIPHTHEROID** bacillus, case of cerebrospinal meningitis due to, [Dick] *84
- DIPLEGIA**, facial, [De Castro] 494
- DIPLOCOCCUS** infection of urinary organs, autogenous vaccine treatment of, [Pfister & Bohme] 1059
- DIPLOMAS**, bogus, held by José Luis Blanco, 1336
- DISCOVERIES**, scientific, awards for, 337, 961
- DISEASE**, change of type of, [Rolleston] *1495
 chronic, 1278—MI
 cold and fever constitute a "disease," 1790—MI
 geographic distribution of, 170—ab
 DISFIGUREMENT, validity of law relative to, 822—MI
- DISINFECTANTS**, liquid, 717—ab
- DISINFECTION**: See also Sterilization
- DISINFECTION**, picric acid for, [Caasegrain] 282
 potassium mercuric iodid for skin disinfection, [McKenna & Fisher] 1283
- DISPENSARY**, municipal, maternity service in, in Los Angeles, [McNelle] 49—ME
 situation in New York City, summary and recommendations, 549—ME
- DISSECTION**, who must make required inquiry before corpses may be used for, 1737—MI
- DISTRICT OF COLUMBIA** January examination, 1418
 July examination, 197
 medical news, 183, 680, 808, 1105, 1408, 1462
 October examination, 620
- DIURESIS**, effect of digitalis on, [Jarisch] 1748
 salt, [Pollag] 834
- DIVERTICULITIS**, congenital, of intestine, [Black] 135
 etiology of, [Willey] 1675
 report of case with acute perforation, [Ball] *722
- DIVERTICULUM**, Meckel's, acute perforation of, by foreign body (fish-bone), report of case, [Hagler & Stewart] *1377
 Meckel's, report of case, [Borden] *1308
 recurrent vesical calculi associated with calculus in diverticulum and contracture of vesical orifice, [Davis] 1798
- DOGFISH**, poison of spiny dogfish, [Evans] 1052
- DOGS**, tuberculosis in, [Pettit] 137
- DOUGLAS' POUCH** and rectum, metastatic cancer of, [Cade & Roubier] 1746
- DRAINAGE**, suction, [Gallindez] 428
 surgical, from biologic point of view, [Horsley] *159, 201—ab, 1536—C
- DRINK** control, what is so-called acientific, 464—E, [Rosewater] 753—C
 valid food and soft drink health ordinance, 756—MI
- DROPSY**: See also Edema
- DROPSY**, pregnancy, [Zangemeister] 216
 war, and nutritional edema, [Maver] *934
- DRUG** addiction, some fallacies regarding, [Hubbard] *1439
 addiction, underlying causes of, [Lambert] 490
 habit forming, illegal sales of narcotic drugs by physicians, 1478—MI
 habit-forming, legislation in Santo Domingo, 1337
 habit-forming, narcotic tremor and its treatment, [Rietz] 1283
 habit-forming, prescribing and furnishing under Minnesota law, 1044—MI
 habit-forming, report of committee on narcotic drug situation in United States, 1324
 habit-forming, state antinarcotic law not in conflict with federal act, 1539—MI
 labeling of, uniformity in, 259
 need of uniformity in nomenclature of official drugs in all countries, 893—E
 official methods of control of remedial agents for human use [McCoy] *1553
 penetration of, into spinal cavity and their disposal, [Hashimoto] 136
 Public Health Service warns against untitled medicaments, 1654
 titles to hide identity of, [Dufour] 1184—C
 use of drugs in oil, [Miller] 1270—C
- DRUGGIST**: See Pharmacist
- DUBOIS' Iodoleine**, 104
- DUCTLESS GLANDS**: See also Secretions, Internal

serum test for, [Gasbarrini] 565
- ECLAMPSIA**, [Pachece] 423, [Villanneva] 988
and wartime conditions, [Gessner] 569
cause of, [Tweedy] 491
origin and treatment of, [Dienst] 292
treatment of, [Hofbauer] 1138, [von Jaschke] 1292
treatment of, by transfusion of blood, [Bell] 1675
- ECTODERMAL** defect, congenital, 1332—E, [Goeckermann] 1350
- ECTROPION**, treatment of, [Martini] 363
- ECZEMA**, cure of, associated with varicose veins, [Leriche] 1678
in infants, [De Cyarzal] 1357
nerves of arterial sheath in causation of, [Leriche] 1678
treatment of, [Elsenstaedt] *667
- EDEMA**, angioneurotic, [Landwehr] 570, [Staffer] 636
as symptom in so-called food deficiency disease, [Bigland] 703
experimental production of, as related to protein deficiency, [Kohman] 1281
extrarenal elimination of cardiac edema, [Heineke] 1428
factors in production of, 1330—E
nephritic, treatment of, [de Renzende] 288
pulmonary, acute, [Brown] 1487
pulmonary, cardinal factors in, 1648—E
pulmonary, experimental, [Laqueur] 568
pulmonary, experimental, for teaching purposes, [Laqueur & Reilingh] 992
puncture in treatment of, [von den Velden] 774
Quincke's, [Bolten] 1060
Quincke's, causes of, [Sieben] 498
war dropsy and, [Mayer] *934
war, some aspects of, 130—E
- EDUCATION**: See also Schools; Universities
- EDUCATION** and licensure, annual conference on, 196
clinical courses in summer term in Vienna, 1471
clinical training in university, [Revsing] 1684
examinations and diplomas, [van Rijnberg] 774
further development of, [Bevan] 757—ab
graduate, [Anders] 546—ME
graduate, for panel physicians, 1112
graduate, in United States, report of committee on, [Wilson] 912—ab
graduate teaching units, 813
ideals and their function in, [Vincent] *1065
improvement in 16 years, [Colwell] 758—ab
individualism in, [Eycleshymer] 968—ME
interrelated medical relations, [Blerring] 912—ab
investigation of conditions in departments of preclinical sciences, report of committee of National Research Council, [Erlanger & others] 1117—ME
laboratory professor and medical sciences in United States, [Stockard] *229
medical examination, [Van Rijnberg] 1806
needs and future of, [Vincent] 750—ab
new plan for medical teaching, 263
obligations of medicine in relation to general education, [Braisted] *1293
opening lecture of course on history of medicine, [Menetriere] 138
plea for state general hospital articulated with county, general and other hospitals, and completion of medical education in University of Missouri, [Nifong] 1280—ab
reform in, [Van Rijnberg] 838
report of committee of Association of American Medical Colleges on pedagogical and, [Carter] 823—ab
report of medical officer of board of, 42
scientific course organized by Board of Graduate Studies, 961
- EDUCATION**, Society for Visual Education incorporated, 959
teachers in preclinical sciences, [Henderson] 1415—C
- EFFORT SYNDROME**: See Beart, Irritable
- EFFUSIONS**, pericardial, precise location of, 953—E
- EGGS**, desiccated, bacteriology of, [Sartory & Flament] 704
effect of egg white injection, [Cohen] 915
- EIGHT-HOUR DAY** in Paris hospitals, 1636
- EIGHTY-NINTH DIVISION MEDICAL ASSOCIATION**, 614
- EJACULATORY DUCT**, absence of, [Ancel] 1655
- ELBOW**, unusual abnormality of, [Brown] 1740
- ELECTRIC** currents, domestic, mishaps from, [Zimmern] 635
shock, literature on, 413
stimulation of peripheral nerves exposed at operation, surgical value of, [Kraus & Ingham] *586, [Burke] 1425
tests of skin sensibility, [Neri] 1801
- ELECTROCARDIOGRAM**, analyzing, [Mann] 1191
changes in form of initial ventricular complex in isolated derivations of, [Willius] 1672
clinical and electrocardiographic observations on inversion and other anomalies of P wave, [Hamburg] 1737—ab
effect of experimental lesions of branches of bundle of His on form of, [Wilson & Herrmann] 1669—ab
of auricle, [Ganter] 1803
value of, [Carter & Greene] 130
- ELECTROCARDIOGRAPHY**, clinical, [Klewitz] 1682
- ELECTRODIAGNOSIS**, electric device for, [Tedeschi] 770
- ELECTROLOGY**, diploma in, 747
- EMBOLISM** due to German bullet, [Fry] 424
operative removal of embolus, [Sundberg] 774
- EMBRYOLOGY**, teaching of histology and, [Waite] 823—ab
- EMBRYOTOMY**, intestinal injury during, [Cartolari] 426
- EMETIN** bismuthous ledid, new vehicle for, [Mayer] 1799
hydrochlorid in endameba dysenteria infection, [MacAdam] 830
in influenza, [Poits] 282
urticaria from, [Savignac & Alivisatos] 832
- EMOTIONS** and endocrinology, [Turró] 566
measurement of, 1266
pulse and respiration reactions to, [Bramson] 1431
- EMPATHIC** index and personality, [Brill] 629
- EMPHYSEMA**, treatment of [Heermann] 989
- EMPLOYEE**, injured, treating himself, 1347—MI
ratification of employment of physician, 1419—MI
- EMPLOYER** not liable for negligence of physician, 198—MI
- EMPYEMA** at Cincinnati General Hospital during influenza epidemic, [Ranschoff] *238
bilateral, staphylococcus pyemia, [Durham] *1516
chronic, [Cauchex] 919
experimental streptococcus; attempts at prevention and therapy by means of vaccine and serum, [Gay & Stone] 1543
influenzal, [Sabroe] 640
mask for differential pressure in treatment of, [Goetze] 925
pathogenesis and treatment of, [Moschewitz] 1795
surgical treatment of, [Grant] 129—ab, [Peugniez] 985
treatment of, [Moszkowicz] 1613
tuberculous, [Duboff] 279
- ENCEPHALITIS LETHARGICA**, association of lethargy with influenza bacillus, [Crofton] 1486
bacteriology of, [Maggiola & others] 1290
bacteriology and pathology of, [Morse & Crump] 915
bilateral sympathetic ophthalmoplegia in, [Cadwalader] *1315
brain in, [Alexander & Allen] 1740
causation of, experimental work on, [Strauss] 1183—C
chronic, [Econome] 989
clinical review of cases in Pacific Northwest, [Hause] *372
delirious and meningoradicular types of, [Bassoe] *1009
diagnosis of, value of nasopharyngeal washings and fluids, [Loewe & Strauss] *1373
eye findings in, [Weeds] 131
green-producing coccus from brain in, [Hause] *884
history, pathologic and clinical features, and epidemiology in brief, [Flexner] *865
hitherto undescribed sign in diagnosis of, [Reilly] *735, [Rosenbeck] 965—C
in horses, 1172—E, [Kraus & others] 1198
in Mexico, 898
in Peru, 745
in pregnancy, [Schulze] *732
in pregnancy and labor, [Garnett] *1315
motor disturbances after influenza and, [Marie & Levy] 1288
myoclonic, [Sicard & Kudelski] 1655, [Sicard] 1547, [Boveri] 1604
recrudescence of, [Netter] 704
sequels and morbid anatomy, [Buzard & Greenfield] 1544
sugar in spinal fluid in, [Dopter] 1545
syphilis and, [Jeanselme] 1545
treatment of, [Netter] 1607
virus of, [Levaditi & Harvir] 1745
Winnipeg epidemic of, [Boyd] 762
- ENCEPHALOMENINGOCELE**, [Versari] 1290
- ENCEPHALOMYELITIS**, acute, [Cleland & Campbell] 979
and cerebral glioma, [Hewe] 557
epidemic, [Stahelin] 1389
history of, [Creekshank] 280
- ENDAMEBA** dysenteriae, house fly as carrier of, [Buxton] 702
dysenteric infection, treatment by emetin hydrochlorid, [MacAdam] 830
- ENDOCARDITIS**, aortic, and aortitis, [MacLwaine] 1486
malignant, with perforation of both mitral and aortic valves, [Conboy & Kretschmer] *154
slow, [Debré] 833
streptococcal ulcerative, of aortic valves in infant aged 6 months, [Dible] 1129
- ENDOCRINE GLANDS**: See Secretion, Internal
- ENDOCRINOLOGY**, speculative science and, 1581—E
- ENDOMYCES** albicans infection of skin, [Tanner & Feuer] 1349
- ENDOTHELIOMA**, diffuse, of placaracnoid, [Pirie] 1606
of pleura, report of case, [McDonnell & Maxwell] *168
- ENTEROCOLITIS**, tuberculous, reentgenology of, [Carman] *1371
- ENURESIS**: See Urine, Incontinence of
- ENZYMES** of pneumococcus, [Avery & Cullis] 1668—ab
- EOSINOPHILIA**, peralient, [Giffin] 55
- EPICONDYLITIS** humeri, so-called, [Dubs] 1289
- EPIDIDYMECTOMY**, [Stern] 559
- EPILEPSY**, [Hartenberg] 64
anaphylaxis as factor in, [Pagniez & Lieutaud] 65
and inherited anosmia, [Alikhan] 1289
and syphilis, [Babonneix] 1288
blastomycetic dermatitis with epileptic seizures, [Mendes] 288
causation and treatment, [Blsgaard & Nervig] 1432
cause of, [Marsh] 1191
dilatation of lateral ventricle in, [Thom] 700
facial nerve in, [Roncoroni] 988
fits and fallacies, [MacRobert] *1000
not ground for annulment of marriage, 1278—MI
polyglandular syndrome with, [Etienne & Richard] 1286
- EPILEPSY**, toxemia in, [Lair & Haddow] 1488
urea content of blood in, [Dufour & Semelaigne] 985
- EPINEPHRIN**, action of amines, amino-acids and, on skeletal muscle, [Okushima] 213
action of curara on output of, from suprarenals, [Stewart & Rago] 700
action of, on heat regulation, [Kondo] 213
and quinin, antagonism between, 465
effect of, on blood pressure, [Bauer] 638
gangrene following injection of sugar solution with epinephrin, [Baudilic] 1681
hypersensitiveness to, in goiter, [Troell] 1138, 1272
in asthma, [Maira] 139, [Hoxie & Morris] 1602
Loewi's epinephrin mydriasis as sign of pancreatic insufficiency, [Cockcroft] 1743
substances resembling epinephrin in blood serum, [Rassers] 1494
unusual effects of, in elderly, [Arnstein & Schlesinger] 1200
- EPINEPHRINISM**, chronic, [Hoxie & Morris] 1602
- EPILOITIS**, [Aimes] 138
- EPITHELIOMA** and chrome ulceration, notification of, 465
pathogenesis of, [Yamagawa & Ichikawa] 1748
squamous-cell, of lip, study of 537 cases, [Broders] *656
subglottic laryngeal thyrotomy in removal of, [Davies] *888
- EPITHELIUM**, inducing rapid growth of, over areas denuded of skin by zinc oxide adhesive plaster, [Peters] 1481—ab
- EQUILIBRIUM** and labyrinth, [Maxwell] 58
- ERGOT**, scarcity of in Netherlands, 1033
- ERUPTION** due to mites in barley, [Loir & Legangneux] 137
with rheumatoid symptoms, [Falcioni] 1801
- ERYSIPELAS**, gangrene of acrotum and skin of penis following, [Seemann] 1358
liability for, 347—MI
treatment of, [Bardachzi] 215
- ERYTHEMA** nodosum and tuberculosis, [Ward] 356
nodosum, atypical, [Denecke] 638
- ERYTHREMIA**, roentgen-ray treatment finally successful in, [Forschbach] 771
- ERYTHROCYTES**: See Blood Corpuscles, Red
- ERYTHROCYTOSIS**, case of, [Kane-matus] 1605
- ERYTHROMELALGIA**, [Bodzu] 636
- ESKIMOS**, tuberculosis among, 1185
- ESOPHAGUS**, artificial, [Hirschmann] 639
cancer of, [Patterson] 135, [Praag & Benjamins] 926
cancer of posteriod region and upper end of esophagus, [Turner] 917
cancer of, radium treatment of, [Dufourmentel] 1196
cancer of, radium treatment of, under roentgen-ray control, [Mills & Kimbrough] *1570
corrosive esophagitis, early treatment of, [Salzer] 1749
impacted foreign bodies in, [Zindel] 431
apasm of, [Guisez] 1354
stenosis, dilatation of, [Berchere] 991
strictures from caustic action, prevention of, [Bonhoff] 1059
- ETHER**, Cotton Process ether, 1474
Du Pont ether, 544
in surgical infections, [Fantozzi] 1132
in treatment of external infections, 748
intra-abdominal use of, [Fantozzi] 1611
- ETHICS**, code of, 636
- ETHMOID**, malignancy of, [Jordan] 1672
- ETHYL CHLORID**, apparatus for use of, with other agents, [Erdmann] *1518
in skin grafting, [Torrance] 1284
- EUCALYPTUS**, oil of, poisoning by, [Auerbach] 498
- EUCATROPINE**, 1231
—Werner, 1231
- EUGENICS**, [Mathé] 771, 900
in Uruguay, 1177

- EUMICINE**, report of Council on Pharmacy and Chemistry on, 652—P
- EUPAD** and **Eusol**, 413
- EUROPEAN** health conditions, 813
- EUSOL** and **eupad**, 413
- EVIDENCE**, admissibility of, touching mental capacity, 1736—MI
- EXANTHEM**, petechial, with pneumococcus meningitis, [Hirsch] 1493
- EXCORIATIONS**, neurotic, [MacKee] 1047, [Pusey & Seneur] 1047
- EXERCISES**, physiology of, [Reamark] 826
- physiologic effects of, in tropics, 1782—E
- value of, in after-treatment of internal diseases, [Quincke] 1059
- EXOPHTHALMOS**, pulsating, ligation of carotid for, [Gomes] 769
- traumatic, ligation of carotid for, [de Lapersonne] 493
- with jugular thrombosis, [Cordier & Rollet] 1356
- EXOSTOSES**, cartilaginous, [Dwyer] 1125, [Marsiglia] 1357
- multiple, true nature of, 539
- EXTRACT**, Organ: See Organ Extracts
- EXTREMITIES**: See also Arm; Leg
- EXTREMITIES**, circulatory disturbances of, importance of early diagnosis in, [Bernheim] 1742
- EYE**: See also Special Structures of Eye
- EYE**, artificial, in antiquity, [Van Duyse] 767
- as a portal of infection in respiratory diseases, [Copper & Enright] *521
- care of, 905—ab
- caustic burn of, from indelible ink or lead, [Elmer] *246
- deviation of head and, in brain disease, [Siciliano] 987
- examination required to determine injury of, 972—MI
- foreign bodies in, [Vinsonneau] 706
- infra-red radiant energy and, [Luckiesh] 353
- injury of, incapacity from, [Sildier-Huguenin] 1680
- myiasis of, [Goldschmidt] 991
- ossification of, [Bussy] 360
- reflex adduction of, [Léri] 495
- sarcoma in, [Ten Doeschate] 709
- EYELASHES**, operations to restore, [Esser] 431
- EYELID**, sarcoma of, [Paulina Satanowsky] 836
- F**
- FACE**, congenital clefts in, [Drachter] 1136
- injuries, validity of law relative to disfigurement, 822—MI
- masks in prophylaxis of contagious disease, [Josefson] 1202
- mask, surgeon's mask for those who wear glasses, [Locke] *1231
- Neuralgia of: See Neuralgia, Trigeminal
- FADS**, "credulity and cures," [Solis Cohen] 122—C
- FALLOPIAN TUBES**, actinomycosis of both ovaries and, [Robinson] 60
- ascaris lumbricoides in, [Nacken] 1749
- cancer of, [Phillips] 216
- nonoperative determination of patency of, in sterility, by intra-uterine inflation with oxygen and production of an artificial pneumoperitoneum, [Rubin] *1017
- FAMILIES**, large, and child mortality, [Hers] 1294
- FARADIC** excitability, more direct method for testing, [Erlacher] 1059
- FAREUS** sedimentation test for pregnancy, 527—ab
- FAT**, comparative food values of fats, 195
- grafts, [Mauchaire] 1355
- in feces and calcium metabolism of infants and young children, [Holt & others] 555, 1125
- in plastic operation on lung, [Stromeyer] 1136
- is fat indispensable for well being? 737—E
- metabolism in diabetes, [Geelmuyden] 1684
- metabolism in health and disease with special reference to infancy and childhood, [Hutchison] 1890
- value of fluid human fat in surgery, [Loeffler] 772
- FAT**, vegetable, digestibility of [Hotnes & Deuel] 828
- FATIGUE**, acetouria from, [Azzo Azzi] 834
- cardiovascular rating as measure of physical fatigue and efficiency, [Schneider] *1507
- FAUCES**, suturing pillars of, [Guthrie] 1425
- FECES**, Charcot-Leyden crystals in, in amebic colitis, [Acton] 631
- fat in, and calcium metabolism in children, [Holt & others] 555, 1125
- incontinence of urine and, in child with spina bifida occulta, improvement in vesical control after operation, [Leopold] *439
- mucor isolated from, of beriberi patients, [Kiyosaki] 561
- nonlactose fermenters in, in influenza, [Sherwood & others] 204
- pus cells in, in summer diarrhea, [Zahorsky] 1280—ab
- simple method for detecting fecal carriers, [Liston & Gore] 1425
- FEERLEMINDED**, menace of homicidal defective, [Meagher] 1271—C
- weight of brain in congenital mental deficiency, [Liab] 561
- FEEDING**: See Diet; Nutrition
- FEEES**, increase in, 900
- increased remuneration for panel physicians, 262, 474
- of attending physicians at duels, 1587
- raised by physicians in Egypt 404
- recovery allowed for professional services, 348—MI
- FEEET**: See Foot
- FELLOWSHIPS** offered, 1654
- Mary Putnam Jacobi, 1585
- of medicine, 615
- FEMORAL** vein, stasis hyperemia by ligation of, [Ritter & v. Winlwater] 568, [Stemmier] 566
- FEMUR**, anomalies in head and neck of, [Zaaijer] 1551
- artificial impaction of, in aged, [Lockwood] 129—ab
- fracture of, [Crisdo] 428
- fracture of neck of, [Wassink] 1806
- fracture of neck of, ambulatory treatment of, [Bradford] 59
- fractures of neck of, recent, [Santy] 1287
- gas phlegmon in, [Hall & Kristensen] 68
- splint for fractures of neck of, [Masland] 1601
- FERNENTS**, defensive, [Damianovich] 428
- present knowledge of, [Roger] 494
- FERRO-MANGANESE** Regent Spring, 1182—P
- FERTILITY**, class fertility, 1530
- FETUS**, movements of fetal lungs, [Balthazard & Piédelfèvre] 1354
- FEVER** and protein intoxication, [Galeotti] 1197
- and cold constitute a "disease," 1792—MI
- associated with fracture of skull, [Wilensky] 1190
- during infancy and childhood, significance of, [Ward] 1482—ab
- elimination of acetone bodies in, [Veeder & Johnston] 555
- Puerperal: See Puerperal Infection
- treatment of, and treatment by fever, [Risquez & others] 1198
- whips up kidney, [Etienne & Druessel] 1285
- FIBRINURIA** in carcinoma of kidney, [O'Connor] 1795
- FIBROID**, pregnancy complicated by, [Applegate] 1127, [de Stawell] 1457
- roentgenotherapy of, [Béclère] 765
- FIBROMA**, roentgen treatment of, [Béclère] 63
- Uterine: See Uterus
- FIBROMYOMAS**, lipolysis in, of uterus, [Kelfer] 1356
- radiotherapy of, [Béclère] 1195
- roentgen-ray treatment of, [Béclère] 768
- FIBROTUBERCULOMA**, laryngeal, [Portmann] 1130
- FILARIASIS**, antimony intravenously in, [Rogers] 1605
- intravenous injection of tartar emetic in, [Macfie] 1285
- treatment of, 412
- FINGERS**, drumstick, and osteoarthropathy, [Hogler] 1360
- hippocratic, [Regnault] 63
- indolent sores on, [Mackenna] 284
- one jointed, an inherited abnormality, [Oddie] 355
- FIRST AID**, duties of pharmacists in matter of, 747
- FISH**, supply of meat and, 1413
- FISTULA**, arteriovenous, analysis of 447 cases, [Callander] 1601
- arteriovenous, effect of, on heart and blood vessels, [Reid] 1048
- branchial, cutaneous manifestations in, [Eddowes] 1284
- gastrocolic, [Firth] 1744
- genito-urinary, [Werneck] 1135
- into kidney, [Serés] 363
- parotid, treatment of, [Weitz] 838
- thoracic, resection of scapula in, [Bosquette] 1287
- vesicovaginal operative treatment of, [Judd] 1798
- vesicovaginal, utilization of transposed uterus for cure of, [Dowman] 1284
- FITS** and fallacies, [MacRobert] *1000
- FLAGELLATES**, intestinal: plea for their pathogenicity, [Barrow] 132
- FLEAS**, experiments with transmitting influenza through, [Engelbroth] 1544
- FLORIDA** medical news, 533, 808, 1722
- state board March examination, 1418
- FLUIDS**, methods of administering saline and other solutions to infants and children, [Aikman] *244
- FLUOROMETER**, [Guilleminot] 768
- FLUOROSCOPY**: See Roentgenography
- FLY** as carrier of endameba dysenteriae, [Buxton] 702
- transmission of disease by, [Roche] 1134
- FOLLICULOSIS** versus trachoma in our schools, [Jervey] 1481—ab
- FOOD** adulteration, 1657
- and Drug Bulletin of New York, 1581—E
- and soft drink health ordinance, 756—MI
- control, bacteriology in, [Jordan] 827
- dehydrated, what should be basis of control of, [Prescott] 1739
- digestibility of, 1403—ab
- habits and health, American, 523—E
- restriction, effect of, during war on mortality in Copenhagen, [Hindhede] *381
- supply, world's, [Taylor] 1790—C
- waste, prevention of, 892—E
- FOOT** and hand prints as records in lesions of peripheral nerves, [Pollock] *943
- care of, [Roux] 1289
- isolated disease of scapoid bone of, [Koritzinsky] 292
- Madura: See Madura Foot
- partial amputations of, end results in, [Irwin] 1193
- prophylaxis in childhood, [Rugb] 135
- rebuilding broken arches, [Cross] 1127
- weak, modern treatment of, [Whitman] *151
- FOOT AND MOUTH DISEASE** in Bolivia, 614
- FORCEPS** for use in placenta praevia, [Hanbidge] *98
- Kielland, [Küster] 292
- new use for cover glass forceps, [Place] *1167
- FOREIGN** born Britons, Germans and Irish living in United States, high death rate of, 1329—E
- FOREIGN BODIES** in children, [Munyo] 212
- in nose, unique, [Voorhees] *672
- priority in suggesting transillumination for, [Kahn] 1536—C, [Benedict] 1790—C
- FOREIGN MEDICAL NEWS**, 41, 115, 187, 334, 536, 613, 684, 744, 812, 898, 960, 1033, 1108, 1176, 1264, 1336, 1411, 1467, 1528, 1586, 1656, 1725
- FORMALDEHYD** in milk, test for, [Gallego] 1747
- FORMITOL TABLETS II**, report of Council on Pharmacy and Chemistry, 1730—P
- FRACTURES**: See also under names of bones
- FRACTURES**, after-treatment of, [Curcio] 1801
- autogenous bone grafting for repair in, of long bones [Martin] 201—ab
- band, new, [Collins] *950
- beef bone splints in, [Brenizer] 559, [Henderaon] *715
- birth treatment of, at Fordham Hospital, [Boorstein] 1795
- FRACTURES**, clamps for, [Remmets] 365
- conservative treatment of, [Rauenbusch] 1803
- correction of displacement of fractured bones, [Bonneau] 425
- glue for traction in, 194
- in the aged, [Heinemann] 990
- irreducible, substitute for open operation in, [Weich] *801
- mobilization versus immobilization, [Toepel] 1480—ab
- old nail extension for, [Nielsen] 1750
- plaster splints in treatment of, [Von Brunn] 1683
- spontaneous, in young infant, with inherited syphilis, [Satanowsky] 212
- sudden death after, [Villar] 832
- treated by bone graft at U. S. Army General Hospital No. 3, Colonia, N. J., [Albee & Weigel] *580
- treatment of, [Alipio Santos] 496
- ununited, autoplasmic repair of, [Robinson] 1279—ab
- wire versus nail extension, [Ansinn] 1431
- FRAMBESIA** in Peru, [Burga] 1548

foreign, in need, help for, 260
French killed in battle, commemorative tablet to, 189
French, tribute to heroes of war among, 812
in chamber of deputies, 261
in liberated regions of France, 686
in rural districts, 1346
needed by government, 472
needed for overseas service, 186
needed in Chihuahua, 1109
needed in Orient, 744
not required to report to defendants, 54—MI
number of new practitioners, 188
of Franciscan Order, 1034
panel, demand increased remuneration, 262
panel, graduate education for, 1112
panel, increased remuneration for, 474
panel, range of service of, 1035
present sociological and economic conditions of general practitioner in Austria, 1470
ratification of employment of physician, 1419—MI
recovery allowed for professional services, 348—MI
relief fund of Belgian physicians and pharmacists closed, 262
routine restoration of a soldier's sight by, in course of a day's work, 1462—E
strike of, 814, 901
struggle between government and profession in Tasmania, 1588
violation by, of speed law, 277—MI
wanted for Dutch colonies, 1528
who died for France, action in memory of, 338
- PHYSIOLOGY** at the Paris aviation show, 471
congress of, 1414, 1529

- PHYSIOLOGY**, national institute of psychology and, as applied to industry and commerce, 1266
teaching of, [Lyon] 824—ab
- PHYSIOTHERAPY** in treatment of injuries of athletes, [Stewart] *947
- PHYSIQUE**, nation's, 1112
- PIA-ARACHNOID**, diffuse endothelioma of, [Pirie] 1606
- PIGMENTS** found in nerve tissues, 531—E
- PILLS**, purgative, 324—T, 392—T
- PILOMOTOR** reflex, [Thomas] 1288
- PINEAL BODY**, effect of feeding pineal body on development, [Slisson & Finney] 1050
role of, in pediatrics, [Gordon] 419
- V. PIRQUET'S** test for tuberculosis in children, value of, [Litchfield] 1053
- PITUITARY**, adenoma of, peculiar syndrome associated with, 531—E
extract, active principles of, [Dudley] 700
extract, and histamine, [Abel & Macht] 281, [Cow] 281
extract, physiologic response to, [Hammett & others] 1671
extract, uterine rupture at term after, complicated by premature separation of placenta, [Maxwell] *1378
interrelation of thyroid and, in growth and development of frog larvae, [Hoskins & Hoskins] 1602
relation of diabetes insipidus to disease of, 398—E
tumors, [Reichmann] 1191
tumors, radiotherapy of, [Jangeas] 832
- PITUITOL** Obstetrical, 1316
Surgical, 1316
- PITYRIASIS** rosea, treatment of, [Fried] 1200
- PLACENTA**, alleged placental functions, [Frank] 47—C, [Hammett] 194—C, 269
as a blood-producing organ, [Domínguez] 288
hydraulic, turgidization of, [Schwarz] 1201
implants, [Romano] 1747
prævia, central, [Mathes] 992
prævia, forceps for use in, [Hambidge] *98
premature separation of, complicating uterine rupture at term following use of pituitary extract, [Maxwell] *1378
rapid expulsion of, [Sklavounos] 559
tumor of, [Margeson] 699
- PLAGUE**, 539, 901, 1412
and leprosy in the Bible, [Bolnet] 704
at Constantinople, [Monziols & Collignon] 1546
bill to suppress, 536
considered an industrial accident, 1111
epidemic, 1787
immunity of fowls to, [Flu] 1201, 1806
immunization against, an argument for controlled experiment, 1719—E
immunization against, experiments on, [Flu] 1806
in Brazil, 1586
in Constantinople, 115
in Mexico, 1586, 1656, 1725
in Netherlands India, 960
in Uruguay, 614
pneumonic, and influenza, [Broquet] 985
Secretary Houston requests appropriation to combat, 469
- PLANTAR** reflex, [Bersot] 1680
- PLASMA** of nasopharynx, [Rogers] 978
- PLASTER**, inducing rapid growth of epithelium over areas denuded of skin by use of zinc oxide adhesive plaster applied directly to raw area, [Peters] 1481—ab
- PLATT'S CHLORIDES**, 903—P
- PLAUT-VINCENT'S ANGINA**: See Vincent's Angina
- PLEURA**, aspiration of pus from, [Pittarelli] 361
effusion, cytology of, [Page] 1129
effusion in young children, diagnosis of, [Martinez Zuvirla] 429
effusion, uncommon case of, [Howk & Herring] 279
effusion with inversion of diaphragm producing abdominal tumor, [Riesman] 1199
endothelioma of, report of case, [McDonnell & Maxwell] *168
- PLEURA**, myoma of, [Kornitzer] 771
suppurations, treatment of, 493
- PLEURISY**, apical [Rouhier] 921
artificial pneumothorax in, [Riccioli] 1058
influenza after, [Lortat-Jacob] 1355
pneumothoracocentesis in, [Riccioli] 1681
purulent, [Dalmazzoni] 1057
purulent, acute, [Wassink] 498, [Villandre] 919
treatment of after-effects of, [Zadek] 1137
tuberculous, mild, recurring, [Dufourt & Ségard] 921
vomica with, [Cardoso] 1427
with heart disease, [Luna Freire] 496
with liver disease, [Furno] 1490
- PLEURO-PNEUMONIA**, Friedländer bacillus pleuropneumonia, [Flandin & Debray] 1055
- PLUMBOPATHY**, satire on cults in medicine, 269—ME
- PNEUMECTOMY**, experimental, [Heuer & Dunn] 1048
- PNEUMOCOCCUS**, antiblastic phenomena in immunity to, [Barber] 133
carriers, [Salier & others] 130
enzymes of, [Avery & Cullen] 1668—ab
pneumococcal value of whole fresh blood, [Bull & Bartual] 1049
septicemia, abdominal reactions in, [Flandin & others] 210
Vaccine immunizing, 393
- PNEUMONIA**, "Anti-Pneumococcal Oil" and camphor in, 46—P
central, [Sofré] 1197
experimental production of pneumococcus lobar pneumonia in monkeys, [Blake & Cecil] 1351
foreign protein therapy in, [Miller] 1598—ab
immunization against, further studies on, in monkeys, [Cecil] 1667—ab
influenzal, in France, pathology of, [Bakwin] 1190
influenzal, intravenous injections of hypertonic glucose solution in, [Wells & Blankinship] *75
influenzal, pathology of, [Walker] 205
influenzal, quinin in, [Caffrey] *1166
intravenous injection of hydrogen peroxid in, [Oliver & Murphy] 983
lobar, experimental, 1168—E
lobar, prevention and serum treatment of, [Cecil] 696—ab
lobar, tactile vocal fremitus in, [Gallotti] 1426
mechanism of recovery from, 1405—E
pathology and pathogenesis of pneumococcus lobar pneumonia in monkeys, [Blake & Cecil] 1351
results of antemortem lung punctures in, and their bearing on mechanism of crisis, [Thomas] 1737—ab
role of lymphatics in pneumonic infection of lungs, 1649—E
shallow breathing and, [Meakins] 486
significance of different types of pneumonia following influenza, and therapeutic indication, [Kline] *1312
tuberculous, [Gonzalez] 1133
- PNEUMOPERITONEUM**, [Ribadeaud-Dumas & others] 210, [v. Tenben] 214, [Weil & Loiseleur] 634, [Mallet & Baud] 635, [Alvarez] 699, [Whitman] *1021, 1029—E, [Stewart & Stein] 1271—C
effects produced on blood picture by oxygen inflation of peritoneal cavity, [Goodman] *1515
- PNEUMO-STREPT-SERIUM**, 342
- PNEUMOTHORACENTESIS** in pleurisy, [Riccioli] 1681
- PNEUMOTHORAX**, artificial, in lung disease, [Henius] 567
artificial, in pleurisy, [Riccioli] 1058
artificial, mishaps with, [Cetrángolo] 836
artificial, necropsy after, [Burnand] 425
artificial, operation and recovery in spontaneous pneumothorax following, [Cocke] 978
artificial, spontaneous hemopneumothorax following, [Heise & Krause] 978
- PNEUMOTHORAX**, Association, International, 613
case of, [Robertson] 1545
experimental and critical work on, [Rist & Strohl] 562
false, [Stüvelman] *12
spontaneous, operation and recovery in, following artificial pneumothorax, [Cocke] 978
- PODOPHYLLUM**, 460—T
- POETRY**, public health, 1721—E
- POISONS**, legislature to permit transmission of, through mails, of, 1108
tablets, coating for, to prevent accidental poisoning, [Phillips] 829
- POLAND**, medical relation with, 538
taking medicines out of, 1176
- POLIOMYELITIS**, [Hurtado] 771
in Argentina, 685
in Uruguay, [Escardo] 496
medical treatment of, [Mackay] 1675
meningitic form of, 103—ab, 803—ab
nasal route of infection in, [Amoss] 914
protection against, 952—E
serum treatment of, [Rowan] 355
treatment of, [Vidal & others] 139
- POLLEN ANTIGEN-Lederle** (Spring type), 1167
- POLLEN EXTRACTS**-Arlco, 1779
- POLYCYTHEMIA**, [Herrnheiser] 1549
primary, 1781—E
roentgen therapy in, [Böttner] 1804
with juxtapyloric ulcer, [Bing] 1432
- POLYDACTYLISM** and phenomenon of regeneration, [Arps] *873
- PORPHYRIURIA** with ascending paralysis, [Löffler] 290
- PORTO RICO** and Virgin Islands, needs of children of, 999—ab
physicians hold meeting, 259
- POST-GRADUATE** medical teaching in London, 119
- POSTMORTEM**: See Necropsy
- POTASSIUM** chlorid, effect of calcium, magnesium chlorid and, on respiratory center, [Tsongane] 562
mercuric iodid for skin disinfection, [McKenna & Fisher] 1283
mercuric iodid, germicidal value of, [Macfarlan] 1671
permanganate in smallpox, [Bender] 1199
- POTATO JUICE**, saccharogenic action of, [McGuire & Falk] 488
- POTT'S DISEASE**, suboccipital, and mastoiditis, [Portmann] 1610
- PREGNANCY** and pulmonary tuberculosis, relation between, [Lindhag] 144
asthma in, [Ruibal Salaherry] 142
blood transfusion in, [Losee] 1421
chemical examination of blood and urine in normal pregnancy and in toxemia of pregnancy, [Losee] 1421
dermatoses of, [Castelló] 923
diabetes and, [Reinhardt] 144
diet in, 254—E
dropsy of, [Zangemeister] 216
edema of larynx in, [Pusateri] 1196
encephalitis lethargica in, [Schulze] *732, [Garnett] *1315
extra-uterine, clinical study of, [Stein]
extra-uterine, delivery of viable child from, [Nubiola] 707
extra-uterine, double, one twins, [Carstens] *1518
extra-uterine, etiology of, [Miller] 60
extra-uterine, ruptured, in uterine cornu, after salpingectomy for previous tubal pregnancy [Douglas] *582
Faræus sedimentation test for, 527—ab
fibroids complicating pregnancy, [Applegate] 1127, [de Stawell] 1487
heart disease and, [Kautsky] 216
fleus in, [Villanueva] 429, [Martin] 1060
in advanced carcinoma of cervix, [Shoemaker] 1797
in double uterus, [Alvaro Esquerdo] 140
in rudimentary horn of bicornate uterus, [Broadhead] *1453
influenza and, [Bentner & Vulliéty] 986, [Schmitz] 989
kidney, genesis of symptoms of, [Eckelt] 144
pyelitis in, [Adeodato] 140
syphilis in, [Cornell & Stillians] 1542, [Young] 1798
- PREGNANCY**, thyroidectomy in, [Ukita] 213, 329—E, [Porter] 479—C
toxemias of early, rôle of carbohydrates in treatment of, [Titus & others] *777
tuberculin reaction during, [Nobécourt] 359
tumors complicating, [Spencer] 766, 983, 1284
utility of influenza-pneumonia vaccines in pregnancy and post-operative conditions, [Benson] 1480—ab
vomiting of, treatment of, [Hofbauer] 1138
- PRESCRIPTIONS**, not required to keep copy of, 417—MI
validity of law taking away right to issue certain, 554—MI
- PRESENTATION**, breach, analysis of 56 cases of, [Halsted] *797
- PRINTING**, medical, 748
- PRIVILEGE** as to physician employed prior to injury, 695—MI
not affected by service being gratuitous, 972—MI
- PRIVILEGED COMMUNICATIONS** and not privileged communications, 417—MI
violation of right of, 1036
testifying indirectly to, 199—MI
- PRIZE**, Academy of Medicine offers, 1265
award of, by Academy of Medicine, 260
award to Escomel, 187
Boas, 1033
for orthopedic research, 471
for prosthetic appliance, 1336
for research on anesthesia, 898
for research on nerves, 536
for work on predetermination of sex, 812
King Umberto, 1033
Lannelongue, 1176
Noble, in medicine not awarded, 115
Oliver-Sharpey, 1033
Parkin, 1725
- PROCAIN**, 620
articular following use of, 1273
- PROCAINE-CALCO**, 31
- PROCTOSCOPE** in general diagnosis, [Durham] 1481—ab
- PROFESSION**, Medical: See Medicine; Physician
- PROFESSIONAL SECRECY**, and Infanticide, 1587
- PROFESSORS**, exchange of, 1532
- PROHIBITION** and death rate, 109—E
and physicians, [Fantus] *1143
bonds not necessary for physicians, 1029—E
does it pay from health standpoint? 1104—E
enforced temperance in Europe, 1407—E
law and the physician, 343, 619
what is so-called scientific drink control, 464—E
Wine of Cardini under, 607—E
- PROPRIETARY** name, short and catchy, dangers of, 1524—E
- PROSTATE**, abscess of, [Randall] 1048
atrophy and hypertrophy of, organotherapy in, [Rohleder] 1804
blastomycosis involving seminal vesicles and, [Parmenter & Simpson] 979
cancer of, treated by radiotherapy, 749
extract, effect of feeding, [Macht] 629
lymphoblastoma, (lymphosarcoma) of, [Quinby] 1603
mechanism of acute retention of prostatic origin, [Leguen] 1288
physiologic and pharmacologic studies of prostate gland; effect of prostate feeding on growth and development of tadpoles, [Macht] 1603
sarcoma of, [Herrick] 1048
secretions of seminal vesicles and, [Böttcher] 1684
syphilis of, [Thompson] 1542
- PROSTATECTOMY**, anatomic results of, [Péblip] 705
indications for, [Rietz] 68
suprapubic control of hemorrhage after, [Barringer] 979
suprapubic, local use of calcium chlorid for prevention of serious hemorrhages in, [Frendenberg] 496
- PROSTITUTES**, diseased, legal quarantine of, 416—MI

- PROSTITUTION**, campaign against venereal diseases and, 1728
- PROTEIN**, daily need of 44.4 gm. of protein and 0.88 gm. of phosphorus, 804—E
- diets, high, and nephritis, 107—E, [Newburg] 341—C
- effects of heavy metal salts on, [Kehoe] 1673
- experimental production of edema as related to protein deficiency, [Kohns] 1281
- factors affecting conservation of, in body, 1650—E
- fever, [Cohen] 915
- foreign protein therapy in lobar pneumonia, [Miller] 1598—ab
- high protein diets and arteriosclerosis in rabbits, [Newburgh & Squier] 1599—ab
- in urine, pathologic importance of, [Lanfranco] 1547
- intoxication and fever, [Galeotti] 1197
- nutritive value of proteins of barley oat, rye and wheat kernels, [Osborne & Mendel] 1049
- requirement of maintenance and nutritive efficiency of bread protein, [Sherman] 488
- sensitization in asthma and hay fever, [Sanford] 1424
- sensitization in normal child, [Baker] 555
- shock reaction, 36—E
- therapy, [van Lier] 1431
- therapy for children, [Czerny & Eliasberg] 1683
- therapy in colitis, [Furno] 1747
- therapy in gonococcal infection, [Trossarello] 1802
- therapy, intravenous, [Gow] 1052
- therapy, nonspecific, [Boyd] 59
- PROTEUS** X, agglutination of, in various children's diseases, [Fiore] 1057
- PROTOPLASM**, death of tissues and the life of, 327—E
- PROTOZOA**, intestinal, in troops in Mesopotamia, [Boulenger] 422
- new bi-flagellated protozoon, [Wight & Lucke] 1673
- PRURITUS** ani, new uses of acrotum in treatment of, 702
- auto-experimental study of, [Jourdanet] 1195
- PSEUDARTHROSIS**, avoidable cause of, [Katzenstein] 1138
- of forearm, treatment of, [Dujarier] 425
- treatment of, [Brunzel] 838
- PSEUDOCOXALGIA** in relation to phthisis, [Veyrassat] 1287
- PSEUDOTHERMAPHRODITISM**, [Méndez] 363
- cause of, [Van den Broek] 1806
- complete masculine, [Schwartz] 285
- PSEUDOHYSTERIA** and hyperthyroidism, [Juarros] 1134
- PSEUDOLEUKEMIA**: See Hodgkin's Disease.
- PSEUDOMELOIDAE** of Peru, [Escomel] 1133
- PSEUDOMYXOMA** peritonei, [Biggs] 200—ab
- peritonei in male subjects, [Seelig] 200—ab
- PSORIASIS** from inherited syphilis, [Martagao] 1747
- PSORIASIS**, internal treatment of, [Sabouraud] 769
- is psoriasis incurrigible, [Hammond] 1051
- treatment of, [Pusey] 133
- PSYCHIATRY** and psychology, [Payse] 1357
- Belgian Society of, 1656
- use of orthoform in psychiatric cases, [Bötcher] 988
- PSYCHOLOGY** and psychiatry, [Payse] 1357
- national institute of psychology and physiology as applied to industry and commerce, 1266
- PSYCHONEUROSES**, accidental and constitutional, [Fernández Sanz] 212
- etiology of neurotic symptoms in child of eight, [Stern] 1603
- somatic causes of, [Dana] *1139
- tuberculous, [Ichok] 1200
- PSYCHOPATHOGRAPHY**, [Valdizán] 430
- PSYCHOSES**: See also Insanity; Neurasthenia; Neuroses; Psychoneuroses
- PSYCHOSES**, acute idiopathic or fulminating, [Ladame] 290
- and goiter, [Phillips] 423
- associated with tetany, [Barrett] 1739
- PSYCHOSES**, blood pressure in, [Euzière & Margarot] 139
- bromid-saline infusion in treatment of, [Jørgensen] 709
- cured by intercurrent influenza, [Damaye] 287
- functional, intestinal pathology in, [Cotton & others] 1484
- myxedematous, [Uyematsu] 913
- neurosyphilis and, [Lowrey] 1740
- significance of sequence of psychopathologic phenomena, [Benou] 833
- suprarenal insufficiency as factor in, [Rossi] 1133
- PUBES**, papular itching eruption of, [Withers] 280
- PUBIOTOMY** in extreme case, [Planell] 769
- PUBLIC HEALTH SERVICE** acquires new hospital, 1034
- appropriation asked for, 404, 613, 899, 960, 1034, 1468
- changes in, 813
- Cumming appointed Surgeon-General, 334
- hospitals, 1265, 1657
- present building requirements, 1110
- report of Surgeon-General of, 336
- takes over army hospitals, 960, 1468
- warns against untried medications, 1654
- PUPERPERAL** infection, vaginal hysterectomy for, [Cadenat] 833
- PULMONARY Tuberculosis**: See Tuberculosis, Pulmonary
- PULSE**, acceleration of, with physical exertion, [Minerbi] 287
- alternans, azotemia with, [Esmein & Heltz] 1489
- anricle and venous pulse in man, [Straub] 1428
- changes in respiration and during reaction of mental processes, [Bramson] 1431
- dissociation of pulse findings in aortic stenosis, [Gallavardin] 918
- rate, voluntary acceleration of, [Cargile] 1672
- research on, [Sahl] 636
- slow, [Arango] 636
- slow, and appendicitis, [Stajano] 142
- slow, diagnosis of, by inspection of veins, [Bard] 632
- venous, [Janowski] 918
- PUPIL** changes in syphilis, 181—E
- reaction to atropin, diagnostic significance of, [Scialiano] 426
- PURGATIVE** pills, 460—T
- PURPURA** annularis telangiectodes (Majocchi's disease), [Weiss] 1672
- during convalescence from typhoid, [Roubier & Brette] 287
- from serum disease, [Meleney] 1670
- hemorrhagic, [Cardoso Fonte] 141
- hemorrhagic, arrest of, by raying spleen, [Stephan] 1494
- in young infant, [Reh] 1354
- infections, [Garzón] 212
- simulating appendicitis, [Fantozzi] 66
- urinary tract purpura: probable entity, [Stevens & Peters] 1483
- with uterine myoma, [Verrotti] 1357
- PYELITIS** of pregnancy, [Adeodato] 140
- prognosis of, in infants for later life, [Rhonheimer] 495
- ureteritis and cystitis cystica, [Jacobson] 1601
- PYELONEPHRITIS**, unusual cases of, [Aschner] *320
- PYEMIA**, otogenous, and sepsis, [Heine] 638
- staphylococcus pyemia: bilateral empyema, [Durham] *1516
- PYLON**, efficient and economical, [Johnson] 917
- PYLOROSPASM**, [Ramond] 1801
- Ramstedt operation for, on adult, [Graham] 559
- PYLORUS**, functional insufficiency of, with duodenal ulcer, [Constantin] 769
- hypertrophy of, with pernicious anemia, [Kleemann] 1358
- insufficiency of, [Bonorino & others] 1354
- new, [Gillon] 703
- stenosis and vomiting, 156—ab
- stenosis of, hypertrophic, [Battay] 1480—ab
- stenosis, prognosis in operated cases of, [Goldbloom & Spence] 1421
- PYLORUS**, ulcer, polycythemia with juxta-pyloric ulcer, [Bing] 1432
- PYOGENIC** infection, autovaccines against, [Lawen & Hesse] 1492
- PYONEPHROSIS**, large ureteral calculus associated with, [Ley] 1425
- PYRAMIDAL TRACT**, defective development of pyramidal-cerebellar system, [Paulian] 495
- disease, leg sign of, [Barré] 426
- PYRETICS** and antipyretics, effect of, on production of catalase, [Burge] 205
- Q**
- QUACKERY**, campaign against, 338
- commission, [Van Rijnberk] 1494
- QUADRUPLETS**, [Fallet] 1167—ab, [Pinard] 1489
- QUARANTINE** against Havana, 960
- maritime, 1111
- of diseased prostitutes, 418—M
- station in Colombia, 898
- QUERY** serum in treatment of aphylis, [Dobransky & Thompson] 1605
- QUININ** and heliotherapy, [Viaie] 1747
- antagonism between epinephrin and, 405
- effects of, on tissues, 462—E
- in malaria, [Cornwall] 1424
- in influenza pneumonia, [Caffrey] *1166, [Campbell] 1343—C
- 1820-1920, 738—E
- pharmacodynamics of, [Cornwall] 423, [McCarrison & Cornwall] 830
- sulphate and calomel tablets, 1269—P
- tissue conservation through action of, 608—E
- R**
- RABIES**: See Hydrophobia
- RACES**, tribal ties in modern nations, 188
- RACHICENTESIS**, chair for, [Williamson] *602, *1455
- RACHITIS**, bone condition analogous to, in child of 5 months, [Brade-Birka] 1353
- causation and treatment of, [Pritchard] 207
- cerebral, [Karger] 1683
- clinical rôle of fat-soluble vitamin and its relation to, [Hess & Unger] *217
- craniotabes and beading of ribs as signs of, [Schwartz] 1795
- fat starvation as cause of, [Hutchinson] 491
- in Germany, [Engel] 561
- nutritional disturbances and, [Pereda y Elordi] 363
- sequelae of, in adults, [Léri & Beck] 1745
- with embryonal bone marrow, [Lenoble] 1195
- RADIANT ENERGY**, infra-red, and eye, [Luckleshi] 353
- RADIO-ACTIVE** mud in treatment of adnexitis, [Chiffollau & Guillard] 1356
- RADIOCARDIOMETER**, [Navarro Cánovas] 429
- RADIOGRAPHY**: See Roentgenography
- RADIOLOGY**, diploma in, 747
- proposed chair of, 961
- RADIUM**, action of, on bacteria, [Lequeux & Chomé] 1054
- Bromide, Radio Chemical Corp., 1316
- Carbonate, Radio Chemical Corp., 1316
- Chloride, Radio Chemical Corp., 1316
- comparison of action of roentgen rays and, [Soiland] 1126
- emanations, condensed, [Laborde] 832
- emanations, pathologic changes accompanying injections of active deposit of, [Bagg] 763
- measurement of, [Stratton] 1731—C
- puncture in treatment of cancer, [Regaud] 1196
- results of exposure of animal ovaries to, [Mauray] *1711
- signal, statement concerning, [Moore] 1115—C
- Sulphate, Radio Chemical Corp., 1316
- therapy, [Baud & Mallet] 1130
- therapy in menorrhagia and metrorrhagia, [Degrais] 1356
- RADIUM** therapy in gynecology, [Fabre] 1129
- therapy in nonmalignant uterine bleeding, [Graves] 1797
- therapy of cancer, [Harrold] 1479—ab
- therapy of cancer of esophagus, [Dufourmentel] 1196
- therapy of cancer of esophagus under roentgen-ray control, [Milla & Kimbrough] *1570
- therapy of cancer of uterus, late results in, [Ranshoff] *163
- therapy of uterine cancer, [Nogier] 1196, [Vital Aza] 1681
- therapy of uterine cancer at Stockholm, [Hansen] 1432
- therapy, restoration of menstrual function lost after, 195
- therapy, technic and record of, [Regaud & Ferroux] 832
- unit of cancer-cells destroying action in irradiation, [Seltz & Wintz] 992
- RADIUS**, fracture of radius and ulna at middle third, treatment of, [Lemon] 1604
- RAILROADS** as source of infection, [Dunlap] 1417—C
- injured in a railroad accident, [Fog] 838
- RAMSTEDT** operation on adult, [Graham] 559
- RAT-BITE DISEASE**, [Bergamini] 66
- spirochete transmission in, 250—E
- RATIONS**, feeding the Argentine field army, 1111
- RAUZYER**, G., death of, 1111
- RAYNAUD'S DISEASE** and manic depressive insanity, [Ward] 1484
- and syphilis, [Giroux] 211
- REACTION**, Tuberculin: See Tuberculosis Reaction
- Wassermann: See Wassermann Reaction
- RECKLINGHAUSEN'S DISEASE** with suprarenal insufficiency, 1664
- RECONSTRUCTION**: See under Soldiers
- RECRUIT**, physical defects among male population, [Comrie] 61
- physical defects as revealed by war, 396—E
- RECTOCOLITIS** of uremic origin, [Bensaude & others] 1800
- RECTOSCOPE**, [Pamboukis] 706
- RECTUM**, cancer of, [Bull] 292
- cancer of Douglas' pouch and, metastatic, [Cade & Roubier] 1746
- cancer, perirectal, [Melchior] 1202
- changes in mucosa following intra-rectal ether narcosis, [Savignac & Vidal] 1354
- plastic operations on, [Stone] 201—ab
- prolapse of, [Heinemann] 1136
- prolapse of, in children, treatment of, [Plenz] 1492
- RECURRENT FEVER**: See Relapsing Fever
- RED CROSS**, American, recognition of services of, by Academy of Medicine of Paris, 1339
- American, special reserve fund, 403
- American, work of, in France, [Lettulle] 1607
- American, work of, in Vienna, 1727
- and Order of St. John unite, 114
- appointments, 114
- bureau of disaster preparedness, 403
- Canadian, departure of, 189
- Christmas seals, 811
- Council, 1336
- crusade against epidemics, 1179
- in charge in Estonia, 898
- league items, 1033
- meeting, delegates to, 536
- next international conference of, 405
- Nova Scotia, work of, 1335
- of Geneva, international committee of, and League of the Red Cross Societies, [Hereford] 820—C
- plans of, 683
- scholarships, 1465
- societies, antituberculosis campaign of, 1726
- societies, league of, 334
- RED CROSS PILE CURE**, 1474—P
- REFLEXES**, abdominal, loss of, in abdominal conditions, [Williams] 1193
- abdominocardiac, [Prevel] 1679
- during sleep, [González] 362
- pillomotor, [Thomas] 1288
- plantar, [Bersot] 1680

- REFLEXES**, significance of Babinski phenomenon, [Friedman] 979
- REFRACTION** in semidarkness, [Wibaut] 709
- REFRIGERATORS**, thermoregulation of, [Strong] 1476—C
- REGISTRANTS**: See **Recruits**
- RELAPSING FEVER**, supranuclear insufficiency in, [Monziols & Collignon] 1546
- REMEDIAL AGENTS** for human use, official methods of control of, [McCoy] *1553
- REPRINTS**, need of uniformity in shape and size of, [Taylor] 543—C
on research in physiology, physiologic chemistry and pharmacology, request for, [Pearce] 1039—C
- REPUBLICAN** platform and health and education, 1720—E, 1724
- RESEARCH**, grants for, 1654
in clinical medicine, [Robinson] 910—ab
in teaching laboratories, [Klotz] 909—ab
Institute of Baking, 1335
Medical Research Council, 1338
medical training for, 1417—ab
promotion of, 1414
rewards for, 1180
work, appropriation for, 114
work at zoological gardens, 338
work, grant for, 9559
- RESPIRATION**, changes in pulse and during reaction of mental processes, [Bramson] 1431
clinical studies on; determination of normal vital capacity of lungs, [West] *1191
- RESPIRATORY** center, effect of calcium, potassium chloride and magnesium chloride on, [Tangane] 562
disease carrier, acute, [Spooner] *582
disease, eye as a portal of infection in, [Copper & Enright] *521
disease, production of, in monkeys by inoculation with bacillus influenzae, [Blake & Cecil] *170
disease transmission by inanimate objects, 1462—E
infections, bacillus bronchisepticus as cause of, [Hoskins & Stout] 915
mechanism, instrument for recording intrathoracic pressure and, [Drachter] 1137
sounds heard on the head, [Myerson] 479—C, [Jacobsen] 619—C
tract, chilling of skin in relation to disease of, [Galeotti] 1491
tract, fate of bacteria introduced into, [Bloomfield & Huck] 628, 1522—E, 1601
tract, fate of influenza bacilli in, [Bloomfield] 1421
tract, infection route in, [Winternitz & others] 1421
volume and alveolar air at low oxygen, [Lutz & Schneider] 353
volume, effect of low oxygen on, [Ellis] 353
- RETINA**, perforation of, [De Jesús] 1612
- RETINITIS** in diabetics, [Cantonnet] 138
- REVILLIOD**, memorial to, 685
- RHEUMATISM**, acute, articular at base hospital No. 6, A. E. F. [White] 1795
eruptive disease with rheumatoid symptoms, [Falconi] 1801
fibrous, [Lereboullet & Mouzon] 1055
gonococcus, serotherapy of, [Debré & Paraf] 63
gonorrheal, treatment by vaccines given intravenously, [Fraser & Duncan] 703
gouty, [Butler] 141
hypothyroidism and, [Lombardi] 1058
in children, [Puchades] 139
incidence of acute rheumatic fever at Bellevue Hospital, [Lambert] *993
tuberculous, [Duvernay] 1489
- RHINOPHYMA**, [Seelig] 129—ab
cure of, by plastic operation with good cosmetic results, [Grattan] *1450
- RHODE ISLAND** medical news, 1632
state board April examination, 1791
state board January examination, 1595
- RHUBARB** as cathartic, 526—T
- RHUS**, poison ivy, oak and aumac, 1258—E, [Hessler] 1475—C, [Irving] 1475—C, [Stoler] 1475—C
- RIBS**, craniotabes and beading of, as signs of rachitis, [Schwartz] 1795
cervical, [Dubois] 62
compression neuritis due to normal first dorsal rib, [Wheeler] 1675
compression of lower trunk of brachial plexus by first dorsal rib, [Stopford] 207
normal, production of pressure symptoms by, 110—E
scorbutic beading of, [Hess & Unger] 1795
- RIBEYRO**, dismissal of, 1265
- RICE**, starvation of pigeons fed with hulled rice, [Lumiere] 1607
- RICKETS**: See **Rachitis**
- RIEDEL'S LOBE** of liver complicating urologic diagnosis, [O'Connor] 1484
- RINGWORM** due to trichophyton, [Hartzell] 280
of nails, treatment of, [Craik] 766
- RIO DE JANEIRO** letter, 539
- ROBINSON** Spring Water, 1182—P
- ROCKEFELLER**, J. D., more gifts by, 40, 1724
- ROCKEFELLER** Foundation commission to study malaria, 263
Foundation donation to Vienna sufferers, 1176
Institute, appreciation of work of, 470
- ROCKY MOUNTAIN SPOTTED FEVER**, [Wolbach] 489
- ROENTGEN**, Prof., retirement of, 1411
- ROENTGEN RAYS**, action of small doses, [Eiken] 216
and metabolism in cancer, [De Niord] 486
burns, release not bar to action for, 128—MI
comparison of action of radium and, [Soiland] 1126
Diagnosis: See **Pneumoperitoneum**; **Roentgenography**
effect of small doses of, on lymphoid deposits, [Murphy] 1738—ab
influence of, on progress of tuberculosis, [Weinberg] 1672
lethal dose of, for cancer cells, [Wood & Prime] *308
lymphocytosis and lymphoid hyperplasia induced by, 1028—E
microbiologic action of, [Vilaplana] 140
precautions in roentgen-ray work, [Gunther] 1130
plates, tax on, 745
sterilization of ovaries, [Guillermín] 426
technic, progress in, [Winter] 215
- ROENTGENOGRAMS**, contour of lungs in, [Chaoul] 1359
demand for injection of collargol not reasonable, 484—MI
- ROENTGENOGRAPHY**, iodine and bromine pastes as used in, [Schanz] *316
of tender points, [Jaulin] 769
of tuberculous enterocolitis, [Carman] *1371
Oxygen in: See **Pneumoperitoneum**
stereoscopic, with bedside unit, [Curl] *28
value of roentgen ray in diagnostic work, [McCaskey] 487
- ROENTGENOLOGIST**, value after death of good will of business of, 127—MI
- ROENTGENOTHERAPY**, dose of, for carcinoma, [Lehmann] 1550
erythema or normal dose in hard-ray roentgenotherapy, [Meyer] 708
exact localization of focus of infection in, of carcinoma of uterus, [Borell] 1551
favorable effect of roentgenotherapy on retarded growth, [Stettner] 989
in gynecology, [Boije] 1431
of cancer, [Regaud] 920
of uterine fibromyomas, [Béclère] 1195
postoperative raying, [van der Haer] 366
saturation in, its estimation and maintenance, [Kingsley] 1350
unit of cancer-cell destroying action in irradiation, [Seltz & Wintz] 992
- ROOS**, P. F. van Hamel, tribute to pure food champion in Netherlands, 1467
- ROSTOCK UNIVERSITY**, 500th anniversary of, 960
- ROUND LIGAMENTS**, interstitial transplantation of, [Wardlow] 60
sarcoma of, [Moench] 1484
- ROYAL** College of Surgeons, election of honorary fellows of, 814
Society of Medicine, war section of, 814
- RUBBER** tubing as cause of reaction to intravenous injection, [Stokes & Busman] *1013, [Goldenberg] 1271—C
- RUBEOLA**: See **Measles**
- RUDOLPH'S** alleged specific for malaria, Antiplasma, 618—P
- RURAL** districts, medical aid in, 1346
hygiene in Brazil, 1109
- RYE**, nutritive value of proteins of, [Osborne & Mendel] 1049
- S**
- SABINE'S** Indian Vegetable Cough Balsam, 1661—P
Indian Vegetable Tea, 1661—P
- SACCHARIN** in urine, determination of, [Jamieson] 487
- SACHS-GEORGI** REACTION, [Wolfenstein] 1136
and Meinicke reaction, [Merzweiler] 837
and Wassermann, comparative investigation of, [Raabe] 707
quantitative technic for, [Bok] 1551
- SACRO-ILIAC** articulation, [Pilatte & Vignes] 139
- SACRUM**, tumors of, [Lund] 132, [Goldthwait] 1048
- ST. ANDREWS** Institute for Clinical Research, 615
- SAINT-BEUVE**, semicentennial of, 41
- SALICYLATES**, effect of, on formation of immune bodies, [Swift] 1668—ab
- SALIVA** in diabetes, [Rathery & Binet] 1801
protection of upper air passages by secretion of mouth and, 252—E
reaction of, [Bloomfield & Huck] 1601
- SALIVARY** calculi, report of 5 cases, [Erdman] *1447
fistulas, treatment of, [Weitz] 838
glands, tumors of, [Elpidio Stincer] 141
- SALPINGITIS** and neoplasms with prolapse of uterus, [Alvaro Esquerdo] 141
- SAL-SANO**, 1115—P
- SALT** as antidote for strychnin, [Giribaldi] 1357
assimilation of inorganic mineral salts, [Grumme] 774
restriction of water and, [Allen] *652
solution, methods of administering saline and other solutions to infants and children, [Aikman] *244
- SALVARSAN**: See **Arsphenamin**
- SANATORIUM**, architecture of, new features in, 413—ME
village for the tuberculous, [Sixto] 364
- SANITATION**, rural, in Brazil, 1337
- SANTAL** Pepsin Capsules, 818
- SANTONIN**, scarcity of, in Netherlands, 1033
- SARCINAE** in stomach, diagnostic significance of, [Gerhardt] 1199
- SARCOID**, Boeck's, [Stumpke] 1493
- SARCOMA**, fowl, [Ogata & others] 1682
idiopathic hemorrhagic, [Cole & Crump] 1047
in frontal sinus, [Galiciotti] 496
malignant, [Emmert] 629
of bone, treatment of, [Calderón] 362
of cerebellum, report of case, [Steuber] 1742
of eye, [Ten Doesschate] 709
of eyelid, [Paulina Satonowsky] 836
of kidney, [Oraison & Faure] 1195
of long bones, treatment of, [Coley] 57
of prostate, [Herrick] 1048
of round ligament, [Moench] 1484
of stomach, [Loeper] 65, [Haggard] 200—ab, [Kimpston] 203, [Koettlitz] 358
of thyroid and pancreas, [Van Rijssel] 1060
of uterus and its relation to roentgenotherapy, [Geist] 752—C
recurring, of ileum, [Battle] 1605
round cell, of arm, [Montgomery] 59
- SARDA**, G., death of, 1414
- SCABIES** and osteomyelitis, [Marti] 428
- SCALDING**, theories in regard to death by, [Pfeiffer] 1292
- SCANDINAVIAN**, Congress of Internal Medicine, 1656
- SCAPHOID** bone of foot, isolated disease of, [Koritzinsky] 292
- SCAPULA**, resection of, in treatment of fistulas, [Bosquette] 1287
- SCAR**: See **Cicatrix**
- SCARLET** FEVER, acute cervical arthritis following, [Mayet & Laval] 1355
biologic study of hemolytic streptococci from throats of patients suffering from, [Dochez & Bliss] 1600—ab
early diagnosis of, [Zuelzer] 1199
jaundice in, [Meurisse] 920
nephritis in, prognosis of, [Duyvis] 570
patient, liability for negligent advice to parents of, 483—MI
renal function in, [Veeder & Johnston] 1125
specific nature of hemolytic streptococcus of, [Tunnicliff] *1386
surgical, [Hutinel] 1607
tardy eruption in, [Mut] 834
- SCHICK** TEST: See **Diphtheria**
- SCHISTOSOMA** mansoni and schistosomiasis observed in Brazil, 1589
- SCHISTOSOMIASIS** and schistosoma mansoni observed in Brazil, 1589
- SCHLATTER-OSGOOD** disease, [Sibuya] 1676
- SCHOOL**: See also **Education**, **Medical**; **University**
Children: See **Under Children**
excluding children from, for trachoma, 554—MI
hygiene and physical education, commission on, 1339
inspection during epidemics, [Azoulay] 1545
larger function of state university medical schools, [Jessup] 825—ab, *1068
medical gifts to, 683
medical inspection of, necessity for examination of ear and nose in, [Gèzes] 1130
of Medicine of Rosario, 1658
- SCIATICA**, electric and roentgen treatment of, [Zimmern] 1130
etiology and pathogenesis of, [Lindstedt] 1750
Lasègue sign in, [Helwed] 1552
signs of, [Bonssy & Cornil] 1288
- SCLERODACTYLIA**, necropsy findings in congenital scleroderma and, [Weidman] 1349
- SCLERODERMA**, diffuse symmetrical, [Henderson] 1798
in relation to disease of endocrine glands, [Roese] 989
necropsy findings in congenital sclerodactylia and, [Weidman] 1349
- SCLEROSIS** combined, due to anemia of pernicious type, [Redwood] *1025
multiple, cerebrospinal fluid in, [Moore] 487
multiple, paraplegic, [Church] *1045
of basal ganglia with hyperthermia, [Mammelle] 1683
- SCOLIOSIS**, Abbott's method of treating, [Joland] 634
- SCORBUTUS**: See **Scurvy**
- SCROTUM**, gangrene of, and skin of penis following erysipelas, [Seemann] 1358
new uses of, [Johnson] 702
- SCURVY**, [Hehr] 1424, [Bierich] 1491
effect of malt and malt extracts on, [McClendon & others] 132
influence of scurvy diet on supranals, [McCarrison] 423
not a bacterial disease, 1169—E
- SEALEAF** Emulsion, 1661—P
- SEASICKNESS**, [Dragotti] 1290
- SECRECTIONS**, INTERNAL, arterial hypertension associated with endocrine dyscrasia, [Engelbach] *1619
in relation to skin, [Oyarzabal] 924
mental cases of endocrine consideration, [Prior] 983
polyglandular disease in acromegaly and other disturbances of hypophysis, [Howard] 202
resolution on sale of endocrine preparations, 1322
- SEELYE'S** Ner-Vena, 1473—P
- SEESSEL** fellowships, 40
- SEMI-LUNAR** bones, dislocation of carpal scaphoid and, [Kleinberg] *312

- SEMINAL VESICLES**, blastomycosis involving prostate and, [Parmenter & Simpson] 979
operative treatment of vesiculitis, [Cunningham] 489
roentgen-ray studies of vasa deferentia and, [Young & Waters] 627
secretions of prostate and, [Böttcher] 1684
- SEPTICEMIAS**, Puerperal: See Puerperal Infection
- SERBIAN** surgeons to be trained in England, 539
- SEROTHERAPY**, prophylactic anti-streptococcus serum for parturients, [Garcia San Martin] 836
- SERRATUS** magnus, isolated paralysis of, [Villaret & others] 1607
- SERUM** SICKNESS, leukocytes in anaphylaxis of, [Barach] 915
- SERUMS** furnished by Paris Pasteur Institute, 963
- SESAMOID** bone of big toe, lesions of, [Serafini] 1289
- SEX** education and birth rate, 1338
hygiene, [Bard] 68
influence of, on pathology of children, 1111
organs and mental diseases, [Desogues] 1611
predetermination of, prize for article on, 812
- SHAVING** brushes, prohibition of importation of, from Japan, 747
- SHELLEY**, the invalid, [Mohr] 206
- SHEPPARD-TOWNER BILL**, 1176
endorsed by health officers, 1585
status of, 1655
- SHOCK**, clinical, hemoclasia in, [Widal & others] 1609
experimental studies on effect of anesthetics in, [Cattell] 1540
—ab
improved methods of treatment of, 106—E
obstetric, [Iraeta] 289
peripheral vasoconstriction in, [Ducastaing] 494
shell, and court-martial for cowardice, 1588
traumatic, [Bosquette & Moulon-guet] 1287
- SHORT STOP**, 1473—P
- SHOULDER**, arthrodesis of, [Serafini] 1289
brachial birth palsy: pseudo-paralysis of shoulder joint origin, [Thomas] 1541
dislocation of, habitual, [Ollershaw] 1740
luxation of, habitual, [Loeffler] 1749
plaster cast for immobilization of, [Taddell] 564
varus deformity of, [Angeletti] 564
- SIGMOID** flexure, anastomosis for volvulus of, [Pochhammer] 1201
flexure, volvulus of, [Ingebrigtsen] 1287
- SINGING**, therapeutic value of, 747
- SINGLETON'S** Eye Ointment and other nostrums, 193—P
- SINGULTUS**: See Hiccup
- SINUS**, accessory sinus disease, diagnosis and prognosis of loss of vision from, [White] *1510
frontal, sarcoma in, [Caliceti] 496
longitudinal, thrombosis of, in influenza, [Szizeti] 1614
- SKEEN'S** Stricture Cure, postal authorities deny use of United States mails to a mail order quack, 340—P
- SKIN**, apparatus for exposure of skin or mucous membrane to vapor of toxic substances; observations on dichlorethylsulphide, [Eyster & Mavor] 1674
as an index to health, [Scholtz] 1543
cancer and solar keratoses, [McCoy] 827
chilling of, in relation to disease of respiratory apparatus, [Gal-leotti] 1491
disease and syphilis, recent progress in, [Gougerot] 210
disease, internal treatment in, [Ravaut] 920
diseases, serodiagnosis in, [Jol-train] 210
disinfection, potassium mercuric iodid for, [McKenna & Fisher] 1283
electric tests of sensibility of, [Neri] 1801
endomyes albicans, infection of, [Tanner & Feuer] 1349
esophylactic (protective) function of, [Hoffmann] 214
- SKIN** flaps, Reverdin, technic for, [Dubreuilh] 493
grafting by means of freezing with ethyl chlorid, [Torrance] 1284
hypersensitiveness of, [Fleischer & others] 55
internal secretions in relation to, [Oyarzabal] 924
microscopic studies of, [Schur] 1292
peculiar fungus infection of skin (soorpilze), [Engman] 1349
senile, congenital, [Variot & Calhau] 767
wrinkled in, children, [Souques] 634
- SKULL**: See Cranium
- SLEEP**, hysterical sleeping attacks, [Carilli] 357
reflexes during, [Gonzales] 362
- SLEEPING SICKNESS**: See Trypanosomiasis
- SMALLPOX** and vaccination, [Sobornhelm] 290
ban lifted, 1175
epidemic of, 1656
in Canada, 186
in Cuba, 36—ab
in Mexico, 960
pitting unremovable, 1732
potassium permanganate in, [Bender] 1199
vaccination, observations on, [Wagner] 1200
- SNAKE**, poisoning, recovery from, [Asana] 208
venom and coagulation of blood, [Houssay & Sordelli] 140
venoms, Brazilian work on, 123
- SOAPS**, medicated, 182—ab
- SOCIAL** hygiene workers needed, 1176
- SOCIETIES**, international organization of medical societies, 962
- SODIUM**, cacodylate, experimental work with, on atretic infants, [Clarke & Dow] 1420
cacodylate, universal exfoliative dermatitis from, [Fusey] 280
chlorid diuresis, [Pollag] 834
gynocardate "A" in pulmonary tuberculosis, [Biesenthal] 1601
gynocardate and morrhuate treatment of leprosy, [Neve] 1799
morrhuate and gynocardate in leprosy, [Neve] 1799
morrhuate and sodium hydno-car-pate in leprosy, [Muir] 1799
morrhuate in tuberculosis, [Gang-guili] 1799
salts, intravenous administration of, in combination, 544
salts of oxalic, citric and tartaric acid, toxic action of, [Hara] 213
- SOFT DRINKS**, bacteriologic examination of, [Stokes] 1739
- SOLAR PLEXUS** sign in abdominal neuropathies, [Franklin] 1055
- SOLDIERS**: See also Army; Recruits: War; Wounds: and under names of various diseases
- SOLDIERS**, bill to transfer medical care of disabled veterans in War Risk Insurance Bureau, 1034
disabled in war, what the government is doing for, 471
disabled sailors and national congress for study of questions pertaining to, 749
discharged, care of, 472
discharged, problem of, 472
gain in weight in, [Gray & Allen] 1732—C
neurosurgical unit in Richmond for, 472
reeducation of disabled Alsatians and Lorrainers, 190
war patients still in hospitals, 814
- SOLUTION ARSPHENAMIN-LOWY**, 1519
- SOLUTIONS**, method of administering saline and other solutions, to infants and children, [Aikman] *244
- SORANUS** of Ephesus, a pediatrician of second century, 1651—E
- SOUTH** wind and pathology, [Helly] 1130
- SOUTH CAROLINA** medical news, 185, 682, 958, 1107, 1263, 1335
state board June examination, 271
- SOUTH DAKOTA** medical news, 682, 1653
state board January examination, 1417
- SOY BEANS** digestibility of steam cooked peanuts and, [Holmes] *798
- SPAIN**, victory for United profession in, 1529
- SPASM**, nodding, in children, [Comby] 1745
- SPASMOPHILIA**, magnesium sulphate in, [Genoese] 211
- SPEECH** Defects: See also Stammering
- SPEECH** defects, care of, 1412
- SPEED** law, violation by physician of, 277—M1
- SPEEDWELL** system for care of infants, [Cahpin] 1484
- SPERMATIC** CORD, hematoma of, [Martin] 705
- SPERMATOCELES** and hydroceles containing spermatozoa, [Winslow] 199—ab
- SPERMATOZOIA**, spermatoceles and hydroceles containing, [Winslow] 199—ab
- SPHYGMOANOMETRY**, [Mourgeot & Groux] 1609
- SPHYGMO-OSCILLOGRAPHIC** cuff, [Mougeot] 285
- SPIDER** venom, 479
- SPINA BIFIDA**, [Vaglio] 707
in adults, [Fermi] 1197
occulta in child with incontinence of urine and feces, improvement in vesical control after operation, [Leopold] *439
operative technic in, [Eastman] *156
- SPINAL** CORD, congenital malformation of, [Demole] 290
studies on anterior horn cells before and after amputation, [Taft] 203
subacute combined degeneration of, [Somerville] 701
tubercle bacilli in, of patient suffering from tuberculous meningitis, [Kretschmer] *247
tumor of, in pregnant, [Meyer] 1293
tumor of, intramedullary, [Feilling] 1606
tumor of, puncture findings with, [Ehrenberg] 1060
tumors, diagnosis of, [Climenko] 1741
- SPINAL PUNCTURES**: See Rachi-centesis
- SPINE**, deforming osteochondritis of, [Scheuermann] 1806
electropuncture of, in tabes, [Pic-clino] 1197
fractures of, treatment of, [Marshall] 626
injuries, renal calculi following injuries of spinal column, causes of, [Hollander] 1199
tuberculosis of, [Calvé] 706
tuberculosis of, in adults, [Doche] tuberculosis of, new brace for, [Morri] *949
tuberculosis of, new frame for, [Morri] *99
tuberculosis of, surgical treatment in, 189
tuberculosis of, treatment of, [Meyerding] 1674
tumors, surgical aspects of, [Sargent] 490
- SPIRITS** and the medical mind, 890
—E, [Johnson] 1343—C
- SPIROCHAETA PALLIDA**, effect of weak acetic acid on, [Goodman] *803
new and easy method for demonstrating, [Coffin] *1457
plurality of, [Pagniez] 1801
- SPIROCHETES**, artefact, 1783—E
modified silver method of staining cilia and, [Imai & Hidaka] 766
transmission in rat-bite fever, 250
—E
- SPIROCHETOSIS**, bronchial, 532—E
bronchopulmonary, [Mendex] 924, [Salomon] 1800
heterogenous, [Pagniez] 209
- SPIROPTERA** carcinomas, [Fibiger] 281
- SPLEEN** and phagocytic activity, [Addison] 625
blind on a spleen tissue diet, [Brinckmann] 774
cyst in, [Bacigalupo & Grosso] 771
echinococcus cyst of, [Cardarelli] 426
extract, influence of, on number of corpuscles in circulating blood, [Downs & Eddy] 1281
rupture of, spontaneous, [Shorten] 356
tumors, morphology of, [Nishikawa] 707
- SPLENECTOMY**, emergency, [Man-chego] 565
for hemolytic jaundice, [Losio] 495
in Banti's disease, [Ceballos] 430
in pernicious anemia, [Spender] 1805
indications for, [Kleeblatt] 773
- SPLENECTOMY**, partial, in treatment of hemolytic anemia, [Speidel & others] 1604
- SPLENOMEGALY**, hemolytic, [Biffis] 495
persistent eosinophilia with hyper-leukocytosis and, [Griffin] 55
splenectomy in jaundice and, [McCunnell] 1744
- SPLINTS**, beef bone, [Brenizer] 559
for fractures of neck of femur, [Masland] 1601
plaster, for fractures, [Von Brunn] 1683
screw tractor for use with Thomas' splint, *886
short caliper, [Patterson] *390
- SPONDYLITIS** and abdominal pain, with discussion of nerve-root symptoms simulating visceral disease, [Vanderhoof] *1689
infectious, and perispondylitis, [Lance & Jaubert] 1680
syphilitic, with negative Wassermann reaction, [Evans & Marshall] 1285
- SPONDYLOSIS**, rhizomelic, and osteomalacia, [Pendre] 565
[Pendre] 565
rhizomelic, in girl, [Schnyder] 1746
- SPOROTRICHOSIS**, [Lane] 1424
of genital organs, [Brainos] 1609
surgical importance of, [Monroe] 361
- SPRUDEL** Concentrated Spring Water, 1182—P
- SPRUE**, cultural studies on case of, [Oliver] *27
in New York, [Sturdevant] 764
is spru endemic in south, [Boyd] 1674
tetany in case of, [Barach & Murray] *786
- SPUTUM** borne disease transmission, [Cumming] 829
relation of sputum bacteria to asthma, [Rackemann & Kessler] 1667—ab
simple technic for concentrating, [Wooley] *525
tuberculous, examination of, by zinc precipitation method, [Fejer & Schulz] 1684
tuberculous, sterilization by sun of, [Tecon] 634
- STAIN**, benzidin-polychrome, for blood, [McJunkin] *17
directions for preparation and use of polychrome methylene blue stain for frozen sections, [Terry] *1775
for diphtheria bacilli, [Albert] *28
for Guarnieri's bodies, [Hess] 771
Mallory's eosin and methylene blue tissue stain, 692
modification of Loeffler's flagella stain, [Shunk] 1603
modified silver method of staining cilia and spirochetes, [Imai & Hidaka] 766
study of brain repair by use of trypan blue: vital staining of macrophages, [Macklin & Macklin] 1350
vital, and oxygen consumption of nerve cells, [Kohn] 710
- STAMMERING** children, 266
- STANNXYL** a tin preparation, 692
- STAPHYLOCOCCUS** Vaccine, [Albus & Aureus] 393
- STATE**, and Territorial Health Officers, conference of, with Surgeon-General, 1585
and Territorial Health Officers to meet, 1176
antinarcotic law not in conflict with federal act, 1539—M1
board examinations, statistics of, 1101—E
board statistics for 1919, annual presentation by Council of Medical Education, 1083
- STENOGRAPHER** not able to bind company for operation, 756—M1
- STERILITY**, causes of, [Brun] 564
colon bacillus in vagina as cause of, [Barbash] 981
nonoperative determination of patency of fallopian tubes in sterility: intra-uterine inflation with oxygen, and production of artificial pneumoperitoneum, [Rubin] *1017
treatment of, [Stippel] 143, [Baastrup] 992
- STERILIZATION**: See also Disinfection
- STERILIZATION**, Arnold, improved device for, [Barnes] *390
artificial, of women, [Winter] 1439
by roentgen exposures of ovaries, [Guillermín] 426

- STERILIZATION** of cystoscopes and ureteral catheters, 1536
of oils by means of ultraviolet rays, [Fairhall & Bates] 763
of surgical ligatures and sutures, study of bacteria encountered in, [Frenger & others] *24
temporary, of female, [Turenne] 60
temporary tubal, [Turenne] 142
- STILLBIRTHS**, infant and child mortality including miscarriages and, [Schwarz] 1420
- STITT**, honorary degree to, 1586
- STODDARD'S** Pinus-Codeia and miscellaneous tablets, 1269—P
- STOMACH**, arteries supplying stomach and duodenum and their relation to ulcer, [Reeves] 1284
cancer of, and vitamin deficiency, [McCarrison] 1676
cancer of, chylous ascites due to, [Hendricks] *869
cancer of, with pulmonary lymphangitis, [Turrettini & Gerber] 1356
contents of fasting stomach, [Pron] 1745
differentiation of disease in liver and, [Leven] 64
electric stimulation of motor functioning of stomach wall, [Bircher] 290
erosions and irritation of vagus, [Nicolaysen] 1191, 1294
functioning, influence of diathermy on, [Setzu] 1802
gases and aerophagy, 1651—E
hourglass, [Pauchet] 559
insufficiency of, signs of, [Labbe] 1053
juice, acidity of, [Baufie] 138
pains in, [Rocha Vaz] 1291, 1802
pathologic physiology of innervation of, [Klee] 1292, 1804
perforation of, acute, [Ramstad] 278—ab
pharmacology of certain drugs, used for effect on, [Bastedo] 486
physiology of, [Ivy] 486
physiology of, recent advances in, [Alvarez] 55
polypoid adenoma removed by gastrotomy, [Novak] *871
protecting coating for the stomach, [Ramond] 635
response of normal human stomach to vegetables prepared in different ways, [Miller & others] 1281
roentgenography of, [Merlo] 427
sarcinæ in, diagnostic significance of, [Gerhardt] 1199
sarcoma of, [Loeper] 65, [Haggard] 200—ab, [Kimpton] 203, [Koettlitz] 358
secretion, effects of diets on, [Crohn & Reiss] 486
secretion, effects of organ extracts on, [Boenheim] 1548
secretion in neurocirculatory asthenia, [Musser] 1795
secretion in young children, [Jacobsen] 1431
secretion of gastric juice, [Cohen] 828
secretion, variations in acidity of gastric juice in vitro, [Barthe & Malgoire] 1195
shape of, [Lier] 1201
syphilis of, [Suermondt] 366, [Lignac] 709
tetany of, and pyloric obstruction, [MacCallum & others] 627
tubes, new metal tip possessing obvious advantages for use in gastric or duodenal tubes, [Lyon] *246
typhoid vaccination followed by disturbances in, [Timbal] 1054
ulcer, [Gallart & Hibas] 923
ulcer, deficient thyroid secretion an etiologic factor in gastric and duodenal ulcers and hyperacid conditions, [Katz] 1741
ulcer, diagnosis and treatment of, [Moynihan] 284
ulcer, duodenal tube reveals occult hemorrhage, [Seidl] 1548
ulcer, gastrectomy for, [Abadie] 359
ulcer, gastric mucosa with, [Fricker] 986
ulcer, interpretation of roentgen-ray findings in diagnosis of peptic ulcer, [McClure & Reynolds] *711
ulcer of duodenum and, [Reinhardt] 708
ulcer of duodenum and, early diagnosis of, [Garcia & Lagos] 139
- STOMACH**, ulcer of duodenum and, early excision of, [Garcia] 427
ulcer of duodenum and, in children, [Theile] 1359
ulcer of duodenum and, late results of surgical treatment, [Sberren] 1353
ulcer of duodenum and, methylene blue in diagnosis of, [Baker] 422
ulcer of duodenum and, modern medical treatment of, [Welss] 282
ulcer of duodenum and, new view on pathology, diagnosis and treatment of, [Hurst] 1604
ulcer of duodenum and, surgery of, [Troell] 708
ulcer, prepylorotomy, [Pron] 285
ulcer, origin of, [Dahl] 1432
ulcer, pain of peptic ulcer is best accounted for by corrosion of gastric juice, [Veerland] 764
ulcer, significance of etiologic factors in treatment of peptic ulcer, [Smithies] *1555
- STOMATITIS**, mercurial, caused by administration of calomel, [Gordin] *1163
- STOOL**: See **Feces**
- STRASBOURG** Faculty of Medicine, reorganized, 496
inaugural exercises of the French University of, 41
University festival, 44
- STREPTOCOCCI**, hemolytic, alimentary protection against, 1260—E
dairy infection with, [Brown & Orcutt] 204
hemolytic, biologic study of, from throats of patients suffering from scarlet fever, [Dochez & Bliss] 1600—ab
hemolytic, in digestive canal, [Davis] 556
hemolytic, in normal throat after tonsillectomy, [Van Dyke] *448
hemolytic, in throat, [Otteraaen] 204
human fecal, [Oppenheim] 556
in milk, 1461—E
in milk, source and significance of, [Jones] 1351
septicemia simulating bile-duct disease, [Quenu & others] 920
varieties of, and constancy, [Clawson] 556
Vaccine, 1519
veridans infections of mouth and throat with reference to neuritis and arthritis, [Hay] 1052
virulence of, and hemolysin, productions, [Longcope & others] 1669—ab
- STREPTOLYSIN**, [DeKruif & Ireland] 1543
- STROPHANTHIN**, certain differences in action of digitals and, [Cohn & Levy] 1598—ab
deterioration of crystalline strophanthin in aqueous solution, [Levy & Cullen] 1050
deterioration of, emphasizes importance of details, 955—E
perfusion of medulla of turtle by, [Bush] 700
salt as antidote for, [Giribaldi] 1357
- STUDENTS**, foreign—for or against, 1659
murder of student in School of Medicine of La Plata, 1657
riots among, in Argentina, 1109
statistics of winter term, in Vienna, 1471
- SUBARACHNOID** meningeal hemorrhage, [Mauriac & Ferre] 1287
to wall off subarachnoid space in operating on brain, [Lemaître] 1680
- SUBOXIDATION** syndrome in childhood, [Kerley] *1226
- SUGAR**, arsenic in, 60 persons poisoned by, 1413
in blood: See **Blood**, sugar in
gangrene following injection of sugar solution with epinephrin, [Baudilio] 1681
in urine: See **Urine**, sugar in
infusion in nephritis, [Rathery & Boucheron] 985
rationing of butter and, in case of invalids, 1266
solution, infusion of, [Zagari] 834
tolerance, [Ohler] 1794—ab
- SUCIDE** as evidence of insanity, 348—Ml
mental condition preceding, 462—E
- SULFERO-SOL**, 818—P
- SULPHUR** in cancerous liver, [Robin] 1489
- SUMAC**, poison ivy, oak and, 1258—E, [Hessler] 1475—C, [Irving] 1475—C, [Stoler] 1475—C
- SUNLIGHT THERAPY**: See **Heliotherapy**
- SUPERNATURAL**, significance of the will to believe in, 890—E
- SUPPURATION**, serologic reaction with, [Ymaz] 427
- SUPRARENAL** function, debated theories of, 326—E
functions of, in white rats, [Exner] 1676
hematoma in, [Bacigalupo & Perazzo] 212
influence of scurvy diet on, [McCarrison] 423
insufficiency and neurofibromatosis, [Chaffard & Brodin] 1489
insufficiency and Recklinghausen's disease, 1664
insufficiency as factor in psychoses, [Rossi] 1133
insufficiency in relapsing fever, [Monziols & Collignon] 1546
lymphosarcoma of, [Burnell] 62
secretion, action of, [Cannon] 353
Substance: See **Epinephrin**
- SUPRARENALCTOMY**, urea excretion after, [Bevier & Shevsky] 56
- SURGEON-GENERAL**, copies of report of, not available, 1177
U. S. Army, report of, for 1919, 116
- SURGEONS** Association of, of Great Britain and Ireland, 471, 1179
contract, under Army reorganization bill, 813
in Danish cabinet, 1033
liability of operating, to pay assistants, 128—Ml
- SURGERY**, anatomy in relation to, [Mayo] *367
blood pressure in, [Miller] *514
blood transfusion before operation in severe secondary anemias, [Williamson] 1545
early reparative, [Descamps] 64
for children, [Jorge] 836
French, during war, [Duval] 563
medical aspects of surgical cases, [Lewis] 1480—ab
plastic repair of defects by "suturing in," [Esser] 567
plastic, tubed pedicle in, [Gillies] 283
postoperative colic pains, [Schwartz] 64
safety factors in, [Frank] 559
surgical experience with natives of French colonies, [Verdelet] 705
- SUTURE**, buried suture-lace, [Dubreuilh] 768
new skin suture material, [Ochsner] 1422
wire, [Knoke] 1059
- SWEAT** glands, changes in, [Colombo] 496
reaction of, 740—E
sweating procedures and secretions of urine, [Brutti] 1750
- SWEENEY** Anti-Syphilitic Compound and Anti-Tuberculous Lymph Compound, 965—P
- SYMBIOSIS**, a biologic theory, 815
- SYMBIOTES**, [Garrahan] 364
- SYMPTOMS**, multiformity of, in response to single stimulus, [De Montet] 636
- SYNCOPE** and vertigo in relation to nervous system, [Loaeza] 1612
- SYNTHESIS**, capacity for, of human and animal cells, [Grumme] 774
- SYPHILIS** and dermatology in 1920, [Millan] 1546
and epidemic encephalitis, [Jeaunselme] 1545
and tuberculous, [Marino & Musio-Fournier] 359, [Tieche] 1196, [Mirande] 1545, [Roberts] 1740
arsenobenzol in, [Gibson] 630
as a factor in eye complications of typhus, [Torres Estrada] 67
at venereal clinic, [Skinner] 1285
bone lesion in, multiple, [Gilbert & Saint-Girons] 704
books on, 620
cataract and, [Smit] 926
civil vs. military, 159—ab
campaign against, 190
congenital, [Moore] 491
congenital, nerve deafness due to, in 3 children, [Kay] *1162
congenital, pathology of, [Fraser] 1671
dental syphilitic chancre, [Goodman] 630
diagnosis of, by culture, [Baeslack & Keane] *392
- SYPHILIS**, epilepsy and, [Babonneix] 1288
experimental, in rabbit, primary infection in testicle, [Brown & Pearce] 1351
fate of thoroughly treated syphilitic children, [Müller & Singer] 213
frequency of, especially in railroad employees, [Stokes & Brehmer] 488
in Argentina, [Beatti] *68
in pregnancy and labor, [Cornell & Stillians] 1542
in South Africa, [Pijper] 632
incidence of, among white and colored troops, [Levin] 59
inherited, and dystrophies, [Hutinel & Stévenin] 633, 919
inherited, ascites with, [Bonorono & Carulla] 835
inherited, defective development in, [Zerbino] 835
inherited, dysenteroid syndrome with, [De Medeiros] 1802
inherited, mediastinitis from, [Castex & Beretervide] 770
inherited neurosyphilis, 710
inherited, rousing of, by intercurrent infections, [Hutinel & Naddal] 286
inherited, spontaneous fractures in young infant with, [Satanowsky] 212
inherited, tardy osteoperiostitis with, [Varisio] 1057
inherited, war in relation to, [Hochsinger] 1200
jaundice in secondary stage of, [Giroux] 425
laryngeal crisis with an unusual complication, [Gregory] *793
lung enlargement in, [Edelmann] 1200
lymphosarcoma and, [Berghausen] 1541
mercuric iodid intravenously in, [Spittell] 917
of anterior horns, case of, [Goodwin] *387
of heart, [Oddo & Matei] 1607
of heart and aorta, neo-arsphenamin in, [Kotny & Müller-Dehan] 1805
of heart, diagnosis of, [Luce] 1804
of nervous system, [Scott & Pearson] 1541
of nervous system and psychoses, [Lowrey] 1740
of nervous system in children, [Monrad] 710
of nervous system, intraspinal treatment of, [Marinesco] 1356
of nervous system, investigation of Massachusetts Commission on Mental Disease, [Raeder] 1739
of nervous system, method of treatment for, [Kolmer] *794
of nervous system, result of treatment of, [Solomon] 354
of nervous system, treatment of, [Vasconcelos] 1427
of prostate, [Thompson] 1542
outline of scheme for writing natural history of, [Brown] *1567
precipitation test for, [Galli-Valerio] 563
pregnancy and, [Young] 1798
prognosis of, in light of recent progress, [Pollitzer] *775
prenatal, with plea for its study and prevention, [Kolmer] 1795
psittis from, [Martagao] 1747
Public Health Service warns against untried drugs in, 1654
pulmonary, [Schroder] 1199
pupillary changes in, 181—E
Quéry serum in, [Dobriansky & Thompson] 1605
Raynaud's disease and, [Giroux] 211
recent progress in knowledge of internal syphilitic disease, [Pontano] 65
recent progress in skin disease and, [Gongerot] 210
Sachs-Georgi test, quantitative technic for, [Bok] 1551
secondary, bladder in, [Zimmermann & Levy] 629
serodiagnosis of, [Morat] 430
serodiagnosis of, standardization of, [Lewis] 424
serologic test for, [Sachs & Georgi] 1805
serologic test for, simplified, [Golay] 361
silver salvarsan sodium in, [Rille & Fruhwald] 568
syphilitic scars of spirit, [Collins] *1216
tertiary, of liver, [Carretti] 835

SYPHILIS, treatment of, [Trimble] 1051
treatment, abortive, and tuberculo-
sis, [Tièche] 1196
treatment, adjuvant medication in,
[Balzer] 359
treatment of, present status of,
[Hesse] 1293
typhoid in, [Lobo] 1198
unusual syphilitic manifestation
resembling juxta-articular nod-
ules, [Goodman & Young] 1541
Uruguay remits import duties on
drugs for treatment of, 41
Vernes colorimeter serologic test
for, [Preiswerk] 921
vessels in syphilis and nicotine
poisoning, [Beneke] 1550
Wassermann control in treatment
of, [Sargent] 1541, [Oettinger]
1541
SYPHILITIC scars of spirit, [Col-
lins] *1216, [Oettinger] 1474—C
SYRINGOMYELIA, constitutional
anomalies and, [Finzi] 1490
pathogenesis of, [Hassin] 555
with Paget's disease, [Marie &
Léri] 63
SYRUP LEPTINOL (formerly Syrup
Balsamea), 1591—P
SYRUP OF THYME, 905

- UREA**, elimination and retention of, [Venza] 1131
excretion, [Austin & others] 1793—ab
excretion after suprenalectomy, [Bevier & Shevsky] 56
in blood in an epileptic, [Dufour & Semelaigne] 985
- UREMIA** and ureic diuresis, [Fornaseri] 1426
catatonias with stupor and, following influenza, [Garcia] 1357
meaning of term, [Veil] 497
uremic meningeal reactions, [Roger] 562
- URETER**, anastomosis, uretero-ureteral, [Peterson] 200—ab
calculi in, causing pseudo-ileus, [Frugoni] 211
calculi, conditions contraindicating operation with stone in kidney and, [Braasch] 278—ab
calculi, operative indications for, [Morales Macedo] 770
calculi, results of operations for removal of, [Judd] 200—ab
calculus, large, associated with pyonephrosis, [Ley] 1425
calculus of unusual size, [Kidd] 560
contractions, experimental studies on, [Satsui] 353
experimental study of ureters ligation: demonstration of late results to ureter and kidney, [Caulk & Fischer] 1283
physiology of kidneys, and [Pfäumer] 1293
stenosis of both ureteral orifices, congenital, [Wason] 1603
stricture, importance of, in abdominal diagnosis, [Massenburg] 148—ab
- URETERITIS**, pyelitis and cystitis cystica, [Jacobson] 1601
- URETHRA**, caruncle of, treatment of, [Crenshaw] 489
obstruction of posterior, congenital, [Young & others] 628
prolapse of female urethra, [Smith] *1639
stricture, impassable, resection of, [Harris] 1053
stricture, plastic operation for, [Stern] *85
subcutaneous pedunculated skin flaps for reconstruction of, [Budde] 925
vein urethroplasties, [Legueu] 1547
- URINARY** calculi with dietetic deficiency, [Padua] 355
calculi, growth of, [Hijmans] 498
tract, autogenous vaccine treatment of diplococcus infection of, [Pfister & Böhm] 1059
tract, purpura of, [Stevens & Peters] 1483
tract, tumors of, in chemical workers, [Oppenheimer] 1613
- URINE**, albumin in, quantitative test for, [Dupuy] 1130
albumin quotient in urine and serum, [Albert] 1358
and hemolytic tests, [Arijon] 1058
antiseptic properties of normal dog urine as influenced by diet, [Hain] 1603
bacteriology of, in renal tuberculosis, [Barney & Welles] *1499
chemical examination of blood and, in normal pregnancy and in toxemia of pregnancy, [Losee] 1421
collection of, from each kidney separately, [Hopkins & Quinby] 1126
correlation of urinary creatinin and muscle tissue, 676—E
diastase in, quantity of, [Salgusa] 561
differentiation of pus cells from leukocytes in, 1536
factors in pathogenesis of calculi, [Ascanio-Rodriguez] 141
glucose in, improved test for detection of, [Haines] *301
hemolytic phenomenon of, in chronic nephritis, [Neufeld] 1199
hydrogen ion concentration of, [Talbert] 626
incontinence of, [Aguilar] 988
incontinence of, in children, [Gonzalez Aguilar] 1291
incontinence of, in children, new treatment of, [Barron] 1481—ab
incontinence of feces and, in child with spina bifida occulta, improvement in vesical control after operation, [Leonard] *439
incontinence of, operation for, [van Rooy] 1201
incontinence, surgical treatment of, in adult female, [Schürmeyer] 419
- URINE**, modified Kjeldahl method for estimating nitrogen, nitrites and tryptophan in, [Carbazol] 1128
of white races living in tropics, [Young] 207
proteins in, pathologic importance of, [Lanfranco] 1547
retention of prostatic origin, acute, [Legueu] 1288
saccharin in, determination of, [Jamieson] 487
secretions of, and sweating procedures, [Brütt] 1750
sugar in, tests for, [Bauzil] 138
test for tuberculosis, [Miche] 706, [Debre & Paraf] 834
vitamins in, [Gaglio] 361
- UROBILINEMIA** and urobilinuria, [Strauss & Hahn] 1431
- UROBILINURIA**, [Brule] 138
and urobilinemia, [Strauss & Hahn] 1431
with cholelithiasis, [Hansen] 1614
with continuous malaria fever, [Reynolds] 1358
- UROLOGY** and the general practitioner, [Schlaginweit] 772
- URTICARIA**, [Lousté] 1546
following use of procain, 1273
probably due to syphilis, [Hollander] 280
- URUGUAY** remits import duties on drugs for treatment of syphilis, 41
- USEFUL DRUGS**, and coming revision of pharmacopeia, [Bastedo] 818—C
- UTAH** state board January and April examination, 1664
- UTERUS**, adnexa and appendix, [Beutner] 216
adnexa, operative recurring inflammation of internal genitals, [Fraenkel] 291
bicornate, pregnancy in rudimentary horn of, [Brodhead] *1453
cancer, basal-cell, [Krompecher] 215
cancer, exact location of focus of infection in roentgen treatment of, [Borell] 1551
cancer, late results in radium treatment of, [Ranshoff] *163
cancer of cervix, [Potherat] 635
cancer of cervix and its treatment, report of case, [Lewis] *1164
cancer of cervix, pregnancy in, [Shoemaker] 1797
cancer of cervix, radium treatment of, [Degrais] 425, [Recasens] 1054
cancer, radical abdominal hysterectomy for, report of end-results, showing large percentage of 5 year cures, [Cobb] *14
cancer, radium treatment of, [Nogier] 1196, [Vital Aza] 1681
cancer, radium treatment of, at Stockholm, [Hansen] 1432
cancer, remote results of operations for, [Violet] 360
curettage, warning against, [Bové] 200—ab
dysentery with uterine disease, [Devic & Bouchut] 1054
double pregnancy in, [Alvaro Esquerdo] 140
fibroid, roentgenotherapy of, [Béclère] 765
fibromas, roentgen treatment of, [Béclère] 63
fibromatous degeneration of, [Castano] 1427
fibromyomas, lipolysis in, [Keiffer] 1356
fibromyomas, radiotherapy of, [Béclère] 1195
fibromyomas, roentgen-ray treatment of, [Béclère] 768
hemorrhage in virgins, [Lataú] 923
hemorrhage, radium treatment of, [Degrais] 1356, [Graves] 1797
hemorrhage, relief of menorrhagia and, by roentgen-ray treatment, [Cole] 1480—ab
hemorrhage, zinc chlorid in, [Helleudahl] 432
hypernephroma in, [Hartman] 919
inguinal hernia of, [Royster] 1675
inversion of, puerperal, [Von Jaschke] 637, [Engelman] 1749
myoma, [Evans] 982
myoma, roentgen-ray treatment of, [Bolje] 1431
myoma, with degenerative changes, [Brady] 628
- UTERUS**, myoma, purpura with, [Verrotti] 1357
prolapse, a chronic disease, 1278—M
prolapse, operative treatment of, [Luque] 212
prolapse, salpingitis and neoplasms with, [Alvaro Esquerdo] 141
prolapse, surgical treatment of, [Botin] 1747
radio-active mud in treatment of adnexitis, [Chifoliss & Guillard] 1356
retroversion, with unusual symptoms, [Herz] 282
rupture, at term, [Curbelo & Garcia] 142
rupture at term after pituitary extract, complicated by premature separation of placenta, [Maxwell] *1378
ruptured ectopic pregnancy in uterine cornu, after salpingectomy for previous tubal pregnancy, [Douglass] *582
sarcoma of, and its relation to roentgen therapy, [Geist] 752—C
stab wound of gravid uterus, [de Tommasi] 564
suspension of, new operation for, [Dubose] 490
tumors of, [Evans] 982
- V**
- VACCINATION**: See also under names of diseases, as Typhoid, Vaccination in
VACCINATION, compulsory, [Ely] 1272—C
compulsory, in Czechoslovakia, 812
crime of, old St. Joe does not take antis seriously, 755
position, 687
state not liable for death of militiaman from inoculation, 198—M
without scar, 252—E, [Defries] 543—C, 619
- VACCINE THERAPY**: See under names of diseases
- VACCINES**, bacterial, in immunization and therapy, [Moody] *391
culture medium suitable for growth of organisms used in, [Norris] 631
in dermatology, [Maute] 1546
in surgical affections, 1178
in therapeutics, [Girard] 1546
new vaccine: bacterial solution, [Hishikari] 1676
- VACUUM**, drainage, [Gallindez] 428
- VAGINA**, artificial, construction of, [Brossmann] 1293
atresia of, [Rojas] 142
colon bacillus in, cause of leukorrhea and sterility, [Barbash] 981
mercuric chlorid poisoning from injections, [Bland] *1227
ventrifixation of, [Fraenkel] 292
- VAGINITIS**, trichomonas vaginalis vaginitis, [DeLee] 1049
- VAGITUS UTERINUS**, [Gjersø] 1552
- VAGOTONIA**, present status of, [Alessandrini] 1801
- VAGUS**, irritation of, and stomach erosions, [Nicolaysen] 1191, 1294
pressure experiment, medicolegal significance of, [Von Teubern] 1492
test pressure on vagus, [Kleemann] 1491
- VAILLANT, JACQUES**, honor to, 1414
- VARICELLA**: See Chickenpox
- VARICOCELE**, operative treatment of, [Jacob] 361
pelvic, 545
scrotal, modified operation for, [Meaker] 62
- VARICOSE** ulcer, simplified treatment of, [Stearns] *172
veins, cure of eczema associated with, [Leriche] 1678
veins, significance and treatment of, [Homans] 1422
- VARIOLA**: See Smallpox
- VAS DEFERENS**, roentgen-ray studies of seminal vesicles and, [Young & Waters] 627
- VEGETABLES**, boiled, for diabetics, [Cambridge] 358, 679—E
carbohydrates in, [Olmsted] 488
carbohydrates in diabetic dietary, 952—E
fats, digestibility of, [Holmes & Deuel] 828
sun-dried, anti-beriberi vitamin content and antiscorbutic property of, [Shorten & Roy] 1424
- VENEREAL DISEASE**, [Cole] 60
acridavine in, [Rosen] 1423
campaign against, [Van Leeuwen] 1201, 1728
campaign against, in Army of Occupation, [Davis] *223

- VENEREAL DISEASES**, campaign against, in Paris district of American Expeditionary Forces, [Moore] *1138
hospital for, 1589
in Germany, statistics on, 613
in Switzerland, campaign against, 755
medical secrecy in, 614
milk injections in, [Trossarello] 1802
peril, 407
physician's duty in prophylaxis of, [van Rijnberk] 1294
prevention of, 94, 813, [Van Leeuwen] 1202, 1294, [Ashburn] *1314
reporting of, [Edler] *1764
sanitary social service based on experience with, [Board] 490
senate committee restore appropriation to combat, 1528
survey, 1724
tests of cure in, 687
valid provisions for quarantining of persons with, 1348—MI
- VENTILATION**, hospital, 885—ab of places of amusement, 616
- VENTRICULOGRAPHY**, localization or elimination of cerebral tumors by, [Dandy] 1283
- VERMIN**, hydrocyanic acid for extermination of, [Lubsen & others] 1614
- VERMONT** state board February report, 1345
- VERNES TEST** for syphilis, [Preiswerk] 921
- VERONAL**: See Barbitol
- VERONAL SODIUM-WINTHROP**, 105
- VERRUCAE**, [Pusey] *97
plantaris, roentgen-ray treatment of, [Hazen & Eichenlaub] *1311
Vlemineckx's solution in, 268
- VERTEBRA**, bony changes in feet following fracture of, [Bryau] 1483
cervical, minor displacements of, [Cyriax] 768
neuralgia from malformation of fifth lumbar vertebra, [Novel-Josserand] 1678
- VERTIGO** and syncope in relation to nervous system, [Loneza] 1612
- VIBRIONES**, agglutination of, [Toyoshima] 213
- VIEIRA DE CARVALHO**, tribute to, 536
- VIENNA**, conditions in, [Wilbur] 967—C
letter, 262
- VINCENT'S ANGINA**, chromic acid in, [Dubreuilh] 1425
spread of, to ear, 1474—ab treatment of, [Capitan] 492
- VIRGIN** Islands of United States, [McClanahan] 970—ME
- VIRGINIA** medical news, 185, 469, 535, 683, 959, 1263, 1384
- VIRUSES**, filtrable, [Ciauri] 287
- VISCERA**, transposition of, with multiple malformations, [Toy & Ellis] *322
- VISION**, diagnosis and prognosis of loss of, from accessory sinus disease, [White] *1510
workmen's compensation with especial reference to loss of, [Allport] *166
- VITAL STATISTICS**, 1788
difficulties of securing, [Plecker] 1039—C
for 1918, 811
of Portugal, 1725
of Uruguay, 1337
- VITALITY**, Condensed, 951
- VITAMINS** and growth, [Houlbert] 360
- VITAMINS**, antineuritic, and artificial feeding of children, [Daniels & others] 55
deficiency and cancer of stomach, [McCarrison] 1676
definition of, 1272
fat-soluble and water-soluble vitamin content of green plant tissues, [Steenbock & Gross] 828
fat-soluble, clinical rôle of, and its relation to rickets, [Hess & Unger] *217
in urine, [Gaglio] 361
preparation of stable vitamin product and its value to nutrition, [Dubin & Lewis] 1541
rôle of, in nutrition, [Lumiere] 1607
thermostability of fat-soluble vitamin in plant materials, [Steenbock & Boutwell] 828
- VITREOUS** body, autolysis of, [Hiljaka] 213
fluid, to prevent loss of, in operations on eyes, [van der Hoeve] 708
- VIVISECTION**, dog's protection bill, 1179
- VLEMINECKX**' solution, 62
for verrucae, 268
- VOCAL**, frenitis in croupous pneumonia, [Gallotti] 1426
therapy, 747
- VOCATIONAL** schools in hospitals, 1412
- VOLUMINATION**, new immunization phenomenon, [Torikata] 1676
- VOLVULUS** as complication of appendicectomy, [Dardel] 563
of cecum: double obstruction, [Smith] 1052
of entire mesentery, case of, [Wise] *1165
of sigmoid flexure, [Forgue] 635, [Eugebrigsten] 1287
of sigmoid flexure, anastomosis for, [Pochhammer] 1201
- VOMICA** with interlobar pleurisy, [Cardoso] 1427
- VULVA**, chronic ulcer of, [Heinsius] 202
- VULVITIS**, erosive, [Driscoll] 827
- W**
- WAR**: See also Army; Soldiers; Wounds
- WAR** as factor in pulmonary tuberculosis, [Bernard & others] 1800
British science in the, 43
effects of, on general health in Vienna, 262
effect of, on growth of children in different social groups, 329—E
French children and world war, 614
in relation to hereditary syphilis, [Hochsinger] 1200
Infants born during, [Jahreiss] 1200
medical and surgical history of, 954—E, 1725
medical and surgical history of, appropriation for, 1337, 1529
medical and surgical history of, resolutions on, 1319
medical and surgical history of, work on, 1657
medical reserve officer in, [Hirschman] *21
profits, physicians, as affected by tax on, 815
Risk Insurance Bureau, bill to transfer medical care of disabled veterans to, 1634
- WART**: See Verruca
- WASHINGTON** medical news, 1654
state board July examination, 621
- WASSERMANN REACTION**, accuracy of, 1102—E
agreement in results of, study of tests performed by 2 laboratories in 3,000 successive hospital admissions, [Solomon] *788
- WASSERMANN REACTION** and mis-carriages, [Goodman] 1283
and Sachs-Georgi test, comparative investigations with, [Raabe] 707
and urine, [Arijsen] 1058
clinical and social value of, [Bejarano] 1357
comparison of Bruck and, [Terada] 61, 1194
contradictions, [Wolbarst] 630
control in treatment of syphilis, [Sargent] 1541, [Oettinger] 1541
frequency of a positive Wassermann in an unselected adult male Indian population, [Iyengar] 1676
Golay's modification of, 543, [Funk] 904—C
lee-box fixation in, [Berghausen] *1166
in blood and urine, [Simon] 831
in leprosy, [Iyengar] 1676
in young children, [Saint Girons] 286
modified, [Wang] 208
new method for procuring blood for, [Owen & Martin] *98
of aqueous humor, [Okazaki] 631
standardization of laboratory tests, [Albert] 341—C
- WATER**, elimination of, by kidneys, [Siebeck] 1291
mineral, 177—T
sterilization of drinking water, [De Biasi] 1490
supply "accident," another, 606—E
typhoid fever from, sufficiency of evidence, 621—MI
- WEATHER** man and the physician, 328—E
- WEICHSBERG-NEISSER** inhibiting phenomenon in bactericidal immune sera, [Thijssen] 1483
- WEIGHT** and resistance to infection, [Stickler] 142
curve of infants, [Lesage] 286
gain in weight in soldiers, [Gray & Allen] 1732—C
standard height and, between two and six, [Schlotz] 1684
- WELL'S DISEASE**: See Jaundice, Infectious
- WELCH**, W. H., unique birthday testimonial to, 1594
- WERTHEIM**, ERNST, death of, 814
- WEST VIRGINIA** medical news, 40, 469, 1032, 1410, 1527
state board January report, 1345
- WHEAT**, nutritive value of proteins of, [Osborne & Mendel] 1049
- WHOOPIING COUGH**, [Cuzzolino] 922
and its prevention, [Sajet & van Gelderen] 774
magnesium sulphate in spasmodic and, [Genoese] 211
prophylaxis of, [Enklaar] 1202
vaccine treatment of, [Parera] 1198
- WILL**, evidence touching testamentary capacity, 1420—MI
- WILLEMS** method of treating joint lesions, 188
- WISCONSIN** medical news, 40, 469, 535, 743, 959, 1107, 1411, 1465, 1528
state board January examination, 1537
state board June examination, 197
state board October meeting, 692
- WLADIMIOFF-MIKULICZ** operation, case of, [Vegas] 1127
- WOLFFIAN** BODY, retroperitoneal congenital cyst probably arising from, [Elder] 978
- WOMEN**, admitted to, Edinburgh College of Surgeons, 744
medical, elect officers, 1466
on General Health Council, majority of, 814
physicians, American, in France, honors for, 335
- WOMEN** physicians, increase of, 615
- WOOD**, SIR, EVELYN, an example of power in old age, 398—E
- WORK**, HUBERT, president-elect, 1331—E
- WORKMEN'S COMPENSATION** acts, physicians' burden under, [Harris] 694—ME
award may be commuted when operation is necessary, 198—MI
before and after amputation, 1419—MI
infection carried from toe to face, 1419—MI
law and industrial diseases, 117
law, validity of law relative to disfigurement, 822—MI
revision of, [Quervain] 1130
with especial reference to loss of vision, [Allport] *166
- WOUNDED**: See also Soldiers; War; Wounds
- WOUNDED** still under treatment in military hospitals, number of, 900
- WOUNDS**: See also under names of organs and regions
- WOUNDS**, Carrel-Dakin treatment of, [Newell] 201—ab
device for intermittent flushing of, [Ballenger & Elder] *1315
infected, immediate sterilization and closure of, [Babcock] *1301, [Hyman] 1663—C
tidal irrigation by means of liquid-tight closure, [Taylor] *1700
treatment of, [Reynès] 704, [Loewe & Magnus] 990
ulcerating, treatment of, [Dürig] 638, [Purckhauer] 773
- WRINKLED** skin in children, [Souques] 634, [Variot & Calliou] 767
- WRIST**, dislocation of carpal scaphoid and semilunar bones, [Kleinberg] *312
- WYOMING** state board February examination, 1417
state board June and October examination, 414
- X**
- XANTHOCHROMIA** in cerebrospinal fluid, [Wallgren] 1750
- XANTHOMA**, generalized, [Spillmann & Watrin] 1546
- XEROPHTHALMIA** in native of gold coast, [Macfie] 1743
- X-RAYS**: See Roentgen-Ray
- Y**
- VALE** School of Medicine, recommendations regarding, 470
- YEAST**, extracts of, for culture mediums, [Ayers & Rupp] 763
from human colon, [Lynch & Draper] 1484
- YELLOW FEVER**, 119, 190
control in Ecuador, [Connor] *650
etiology of, [Noguchi] 1134
immunologic studies in, [Noguchi] 914
in Brazil, 1725
in Guatemala, [Madrid] 66, 288
in Guayaquil, Ecuador, in 1918, [Elliott] 762
in Mexico, 115
Noguchi's research on, [Noguchi] 496
serum therapy of, [Noguchi] 914
- Z**
- ZAEGEL'S** Essence and Lung Balsam, 1114—P
- ZINC** chlorid in uterine hemorrhage [Heelendall] 432
precipitation method, for examination of tuberculous sputa, [Fejer & Schulz] 1684
- ZIONIST** unit, work of, 260

AUTHOR INDEX

In this Index are the names of the authors of articles which have appeared in THE JOURNAL, the names of those who have read papers before Societies as published in THE JOURNAL and those whose articles have been abstracted in the Current Medical Literature Department. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL. The author's name is followed by a brief clue to the subject of the article in brackets.
